Abstract

Let \( A \) be a finite-dimensional algebra given by quiver and monomial relations. In [18] we see that the Ext-algebra of \( A \) is finitely generated only if all the Ext-algebras of certain cycle algebras overlying \( A \) are finitely generated. Here a cycle algebra \( \Lambda \) is a finite-dimensional algebra given by quiver and monomial relations where the quiver is an oriented cycle. The main result of this thesis gives necessary and sufficient conditions for the Ext-algebra of such a \( \Lambda \) to be finitely generated; this is achieved by defining a computable invariant of \( \Lambda \), the smo-tube. We also give necessary and sufficient conditions for the Ext-algebra of \( A \) to be Noetherian.

Let \( A \) be a triangular matrix algebra, defined by algebras \( T \) and \( U \) and a \( T-U \)-bimodule \( M \). Under certain conditions we show that if the Ext-algebras of \( T \) and \( U \) are right (respectively left) Noetherian rings, then the Ext-algebra of \( \Lambda \) is a right (respectively left) Noetherian ring. An example shows the hypotheses used cannot be improved. We also specialise to the case where \( \Lambda \) is a one-point extension: we give a specific presentation of a result that parallels a similar theorem for the more general case above.
Acknowledgements

This PhD thesis was researched at the University of Leicester. The author thanks EPSRC for their support, given by way of a Departmental Training Award, and both examiners for pointing out errors and improvements. I would like to thank Øyvind Solberg and Ed Green for their helpful discussions; also Steffen König for answering innumerable questions and André Fonseca for his shared interest in discussing things both mathematical and not. But especially I thank Nicole Snashall, under whom this thesis has been supervised, for all the time, energy and expertise given to this project.

Introduction to the thesis

In this thesis we study the homological properties of finite-dimensional algebras. In particular we present methods whereby certain classes of algebra quickly yield the information of whether their Ext-algebras are Noetherian, finitely generated or infinitely generated.

The use of cohomology to study topological spaces began in the first half of the twentieth century as a powerful way to classify such spaces. Not soon after, Eilenberg and others realised the parallel applications to algebraic structures [8]: the subject then exploded onto the scene, and is used today in almost every branch of algebra.

The two most used objects in this area are the cohomological Ext and the homological Tor: they come from applying respectively the adjoint functors Hom and tensor product to a projective resolution of a module over some ring. The Ext-groups appear almost everywhere to the algebraist, and have become an essential tool. From the study of modular representation theory [7] to tilting theory [19] and to the study of the derived category [25] the Ext-groups are fundamental. In particular, for some ring $R$, the Ext-groups of mod-$R$ can be realised precisely as homomorphism groups of certain degree in the derived category. The importance of the derived category cannot be understated. For instance, a derived equivalence between algebras often relates information from one to the other (see [26], where derived equivalent self-injective algebras are shown to have the same representation dimension). This demonstrates how vital the Ext-groups are to fundamental mathematical concepts. All this being said, there is more to Ext than the Ext-groups on their own. If we collect all the Ext-groups together then we have a graded Abelian group, which we denote $\text{Ext}^*_R(M,N)$, for some ring $R$ and some $R$-modules $M$ and $N$. We can take this group structure to be an additive structure. If, however, we further have that $M = N$, we can define a multiplication. This is called the Yoneda product and is given as:

$$
\text{Ext}^*_R(M,M) \times \text{Ext}^*_R(M,M) \longrightarrow \text{Ext}^{n+m}_R(M,M)
$$
The direct sum of Ext-groups together with the Yoneda product defines a non-negative \( Z \)-graded ring, when \( \Lambda \) is a \( k \)-algebra, \( E(\Lambda) \) is a \( k \)-algebra. This multiplication gives a new level to the information on Ext. One of the most important cases is when the module \( M \) is the direct sum of one copy of each of the simple modules; it is this which we call the Ext-algebra. When \( \Lambda \) is a \( k \)-algebra, \( E(\Lambda) \) is a \( k \)-algebra.

An interesting development is the study of Koszul algebras. The Ext-algebra of the Ext-algebra of a Koszul algebra \( A \) is isomorphic as an algebra to \( A \). Koszul rings must be quadratic \([5]\), but knowing you have this Koszul-duality can lead to other results about your algebra; see for instance Mori’s paper \([22]\), where, for a Koszul algebra, the Poincaré series of certain modules is shown to be a rational function.

In group-theory, group-algebras have long been studied, and the support-variety of a finite-dimensional module over a group-algebra has been defined using the Ext-algebra. More recently Snashall and Solberg have extended this definition to all finitely generated modules over an Artin algebra: the definition still utilises the Ext-algebra. However, the Ext-algebra of a finite-group algebra is always finitely generated: this is certainly not always so for Artin algebras in general. Thus, in computing the support-variety of a module over an Artin algebra, one must tackle the issue of whether or not, for your algebra, the Ext-algebra is finitely generated.

It is well known that a Noetherian ring has many desirable properties; and also that Noetherian and finitely generated are distinct but closely related conditions. Thus the problem of when one can say that the Ext-algebra of a certain algebra will be Noetherian, finitely generated or infinitely generated is the motivation for this thesis.

The class of Artin algebras is a huge one. In order to get a handle on just what conditions might affect the Ext-algebra in the ways described above, we want to consider a subclass of algebras that is easy to work with and at the same time of sufficient complexity to allow us to generalise any results might we get. The class of monomial algebras is that which we choose to study. By the results of Green and Zacharia \([18]\), and others before, we have a very nice description of the Ext-algebra of a monomial algebra. However, as can be seen from Theorems 2.4.17 and 2.5.1, the Ext-algebra of a monomial algebra can still display a wide range of behaviour.

One of the main results of this thesis, Theorem 2.4.17, gives necessary and sufficient conditions for the Ext-algebra of a cycle algebra to be finitely generated. A cycle algebra is a finite-dimensional algebra given by quiver and monomial relations where the quiver is an oriented cycle. In building up to Theorem 2.4.17 we present a
fast method for determining if these conditions hold. This is motivated by Green and Zacharia's result [18, Proposition 1.6] (but see also Section 1.2 of this thesis), which states that the Ext-algebra of an arbitrary monomial algebra given by quiver and relations is finitely generated only if the Ext-algebras of certain cycle algebras are all finitely generated. Using the same machinery that we use for finite generation of the Ext-algebra, we also give necessary and sufficient conditions for the Ext-algebra of Λ to be Noetherian. Other main results are Theorems 4.2.5 and 4.2.9. These respectively detail conditions under which the Ext-algebra of a triangular matrix algebra can be said to be right or left Noetherian.

The thesis is structured as follows. In Section 1.1 we introduce Λ as a cycle algebra and $E(\Lambda)$ as its Ext-algebra; we set up a lot of the notation. Section 1.2 expands upon Green and Zacharia's comments in [18] and explains exactly the known relationship between the Ext-algebra of a monomial algebra and its overlying cycle algebras. In Section 2.1 we return our focus to cycle algebras, and present a convenient way of representing the basis elements of $E(\Lambda)$: the smo-tube $T_{\Lambda}$. This is improved in Section 2.2, where Theorems 2.2.3, 2.2.5 and 2.2.12 give conditions on the smo-tube that speed-up its calculation. Section 2.3 demonstrates the existence of natural constraints on $T_{\Lambda}$, culminating in Theorem 2.3.14, which serves to reduce computational work even further. This section paves the way for Section 2.4 where our first main result, Theorem 2.4.17, gives necessary and sufficient conditions for the finite generation of $E(\Lambda)$. We then give some special cases of this result. In Section 2.5 we give necessary and sufficient conditions for $E(\Lambda)$ to be a Noetherian ring. In Section 3.1 we introduce the triangular matrix algebra and two categories that conveniently represent the module category. In Section 3.2 the notion of a triangular matrix algebra is specialised to a one-point extension. We also construct a one-point extension “from the ground up”. Section 3.3 contains some useful results from ring theory. In Section 4.1 we prove Theorem 4.1.2, which states that if the Ext-algebra of a finite-dimensional algebra is right Noetherian then so is the Ext-algebra of a one-point extension. We also give a lengthy example. In Section 4.2 we generalise Theorem 4.1.2 to produce our final main results: Theorem 4.2.5 and its dual Theorem 4.2.9. We then give an example demonstrating that Theorems 4.2.5 and 4.2.9 are in some sense as much as we could hope for. In the final chapter we give problems of interest generated by this thesis, and some ideas for the future.
Chapter 1

Introduction to maximal overlap sequences

1.1 Background & Preliminaries

Here we introduce notation to be used throughout this chapter and the next.

Let $Q$ be an oriented cycle with $n$ vertices and $n$ arrows. Label the vertices with the natural ordering $1, \ldots, n$ so that there is one arrow from $i$ to $i+1$ for $1 \leq i < n$ and one arrow from $n$ to $1$. Let $\mathbb{k}$ be an algebraically closed field, $I$ an admissible ideal of the path algebra $\mathbb{k}Q$ with a minimal generating set $\rho$ of $m$ monomial relations, which we fix, such that $\mathbb{k}Q/I$ is a finite-dimensional algebra. We say that a path in $\mathbb{k}Q$ is a relation if and only if it is in the set $\rho$. Hereinafter we let $\Lambda = \mathbb{k}Q/I$, reading paths from left to right. Let $r$ denote the Jacobson radical of $\Lambda$, and let $\tilde{A} = \Lambda/r$. Then the Ext-algebra of $\Lambda$, denoted $E(\Lambda)$, is the graded $\mathbb{k}$-algebra $Ext^*_{\Lambda}(\tilde{A}, \tilde{A}) = \bigoplus_{i \geq 0} Ext^i_{\Lambda}(\tilde{A}, \tilde{A})$, with multiplication the Yoneda product.

We now give some further notation that will be required. Let $p$ be a path in $\mathbb{k}Q$. We denote by $\ell(p)$ the length of $p$ and by $o(p)$ and $t(p)$ the start and end vertices of $p$ respectively. A path $q$ is an initial subpath of $p$ if $p = qs$ for some path $s \in \mathbb{k}Q$. A path $q$ is a terminal subpath of $p$ if $p = rq$ for some path $r \in \mathbb{k}Q$.

Define a cycle algebra $\Lambda$ to be a quotient of a path algebra that has an oriented cycle $Q$ for a quiver, and that has monomial relations. Then we have a very nice description of the Yoneda product for $E(\Lambda)$ via maximal overlaps of these relations. We recall the basic definitions from [13] and recursively define certain sets of paths denoted $Q_{\geq i}$. Let $Q_0$ be the set of trivial paths of $Q$, $Q_1$ the set of arrows and set $Q_2 = \rho$. Let $B$ be the usual basis of $\mathbb{k}Q$ consisting of all finite paths, and let $M = \{ b \in B : \text{no subpath of } b \text{ lies in } \rho \}$. For $z \geq 1$, a path $p$ in $\mathbb{k}Q$ is a $z$-prechain if
$p = qwu$, where $q \in Q_{z-1}$, $qw \in Q_z$, $u \in M - Q_0$, and $wu$ has a subpath in $\rho$. Call a $z$-prechain a $z$-chain if no proper initial subpath is a $z$-prechain. Then $Q_{z+1}$ is defined as the set of all $z$-chains, $z \geq 1$. Note that the previous definition of $Q_2 = \rho$ is consistent with this inductive definition.

These $z$-chains correspond to the paths of maximal overlap sequences of [12], [18] and also [4]. The terminology is understood in the following way. Let $s, t \in \rho$. The relation $t$ is said to overlap the relation $s$ if there are paths $X, Y$ in $kQ$ such that $Yt = sX$, with $1 \leq \ell(Y) < \ell(s)$ and $1 \leq \ell(X) < \ell(t)$. This is illustrated in the following diagram.

\[
\begin{array}{c}
\downarrow \quad \downarrow \\
Y \quad X
\end{array}
\]

It is then clear that if $t$ overlaps $s$, the path $sX$ is a $2$-prechain. Moreover we say $t$ maximally overlaps $s$ if $t$ overlaps $s$ and, further, $t$ is the only relation, apart from $s$, that is a subpath of $Yt$. If $t$ maximally overlaps $s$ then $(s, t)$ is a maximal overlap sequence and $sX$ is the underlying path of $(s, t)$. In this case the path $sX$ is a $2$-chain and so $sX \in Q_3$. More generally, for $z \geq 3$ and $s_2, s_3, \ldots, s_z \in \rho$, $(s_2, s_3, \ldots, s_z)$ is a maximal left overlap sequence with underlying path $X_2X_3 \cdots X_z$ if

(i) $X_2 = s_2$,

(ii) $1 \leq \ell(X_i) < \ell(s_i)$ for $i = 3, \ldots, z$,

(iii) There exist paths $Y_3, \ldots, Y_z$ with $X_iX_{i+1} = Y_{i+1}s_{i+1}$ for $i = 2, \ldots, z - 1$,

(iv) $s_3$ is the only relation, apart from $s_2$, that is a subpath of $Y_3s_3$,

(v) $s_i$ is the only relation that is a subpath of $Y_is_i$, for $i = 4, \ldots, z$.

The above conditions are visualised thus:

\[
\begin{array}{c}
\downarrow \quad \downarrow \\
\begin{array}{c}
Y_3 \quad Y_2 \quad Y_1 \\
\downarrow \quad \downarrow \quad \downarrow \\
X_5 \quad X_4 \quad X_3
\end{array}
\end{array}
\]

The path $X_2X_3 \cdots X_z$ is a $(z - 1)$-chain and is thus an element of $Q_z$. The degree of the maximal left overlap sequence $(s_2, s_3, \ldots, s_z)$ is $z$. Throughout the thesis a
maximal left overlap sequence will be used interchangeably with its underlying path and will usually be illustrated thus:

\[ \begin{array}{c}
S_3 \\
S_2 \\
S_4 \\
\vdots \\
S_{2(k-1)} \\
S_2k-1
\end{array} \]

Note that if for some \( z \geq 3 \), \( P^z = (s_2, s_3, \ldots, s_z) \) is a maximal left overlap sequence with underlying path \( X_2X_3 \cdots X_z \) then so is \( P^{z-1} = (s_2, s_3, \ldots, s_{z-1}) \) with underlying path \( X_2X_3 \cdots X_{z-1} \). We call \( X_z \) the path of unoverlapped arrows of \( P^z \). Note that \( P^z = P^{z-1}X_z \).

**Example 1.1.1** Let \( \Lambda = \mathbf{k}Q/I \) be a monomial algebra with \( \mathbf{k}Q \) containing the following path:

\[ 1 \rightarrow \eta_1 \rightarrow \eta_2 \rightarrow \eta_3 \rightarrow \eta_4 \rightarrow \eta_5 \rightarrow \eta_6 \rightarrow \eta_7 \rightarrow \eta_8 \rightarrow 9 \]

and suppose further that \( t_1 = \eta_1\eta_2\eta_3\eta_4 \), \( t_2 = \eta_3\eta_4\eta_5\eta_6 \), \( t_3 = \eta_4\eta_5\eta_6\eta_7 \) and \( t_4 = \eta_6\eta_7\eta_8 \) are the relations of \( \Lambda \) that lie wholly along this path. Let \( S_i \) be the simple module corresponding to the vertex \( i \). Then the path \( t_1 = \eta_1\eta_2\eta_3\eta_4 \) is a maximal overlap sequence of degree 2 (and hence a 1-chain) and represents a basis element in \( \text{Ext}^2(S_1, S_6) \), illustrated thus

\[ \begin{array}{c}
t_1
\end{array} \]

The path \( \eta_1\eta_2\eta_3\eta_4\eta_5\eta_6 \) is a maximal overlap sequence of degree 3 (and hence a 2-chain) and represents a basis element in \( \text{Ext}^3(S_1, S_7) \), illustrated thus

\[ \begin{array}{c}
t_2 \\
t_1
\end{array} \]

The path \( \eta_1\eta_2\eta_3\eta_4\eta_5\eta_6\eta_7 \) is a maximal overlap sequence of degree 4 (and hence a 3-chain) and represents a basis element in \( \text{Ext}^4(S_1, S_9) \), illustrated thus

\[ \begin{array}{c}
t_2 \\
t_1 \\
t_4
\end{array} \]

The path \( \eta_1\eta_2\eta_3\eta_4\eta_5\eta_6\eta_7 \) is not a maximal overlap sequence and so is not a \( z \)-chain for any \( z \geq 0 \). It is however an overlap sequence and so it is a 2-prechain. The diagram below shows the overlap

\[ \begin{array}{c}
t_3 \\
t_2 \\
t_1
\end{array} \]
There is an analogous concept of a maximal right overlap sequence. In fact from [4] we know that the underlying path of a maximal left overlap sequence of degree \( z \) is also the underlying path of a maximal right overlap sequence of degree \( z \) and vice versa. Henceforth we refer to such a path as the underlying path of a maximal overlap sequence; however the construction will always be considered as from the left. We comment further in Section 2.5.

These maximal overlap sequences are of major importance, since they describe a minimal projective resolution of \( \Lambda \). Following our notation, for \( z \geq 0 \) the \( z \)-th projective \( P_z \) in such a resolution is given in [12] as

\[
P_z = \bigoplus_{p \in Q_z} e_p \Lambda,
\]

where \( e_p \) is the trivial path at \( t(p) \). For each \( p \in Q_z \) there is a corresponding element \( e_p^z \) in \( \text{Ext}^2_{\Lambda}(\tilde{\Lambda}, \Lambda) \). This element \( e_p^z \) is represented by the \( \Lambda \)-homomorphism \( h_p^z \in \text{Hom}(P_z, \Lambda) \) given by

\[
h_p^z(e_p^z\lambda) = \begin{cases} 0 & \text{if } p \neq q \text{ in } kQ, \\ e_p^z\tilde{\lambda} & \text{if } p = q \text{ in } kQ, \end{cases}
\]

where \( \tilde{\lambda} \) is the image of \( \lambda \) under the canonical surjection \( \Lambda \rightarrow \tilde{\Lambda} \). Each set \( Q_z \) is identified with a \( k \)-basis of \( \text{Ext}^1_{\Lambda}(\tilde{\Lambda}, \tilde{\Lambda}) \) in the obvious way by taking \( p \) in \( Q_z \) to \( e_p^z \) in \( \text{Ext}^1_{\Lambda}(\tilde{\Lambda}, \tilde{\Lambda}) \).

The set \( G_z := \{ e_p^z : p \in Q_z \} \) is a basis for \( \text{Ext}^1_{\Lambda}(\tilde{\Lambda}, \tilde{\Lambda}) \) and from [18] we have that the union of all the \( G_z \), for \( z \geq 0 \), forms a multiplicative basis for \( E(\Lambda) \). This means that for \( e_p^z \in G_z \) and \( e_q^w \in G_w \), either \( e_p^z e_q^w = 0 \), or \( e_p^z e_q^w \in G_{z+w} \). The one-to-one correspondence between \( Q_z \) and \( G_z \), for each \( z \geq 0 \), given in [18], means that for the remainder of the thesis we may deal with maximal overlap sequences as if they themselves form the multiplicative basis of \( E(\Lambda) \). With this identification, a maximal overlap sequence of degree 0 is a trivial path, and a maximal overlap sequence of degree 1 is an arrow. If \( P^{z_1} \) and \( Q^{z_2} \) are maximal overlap sequences of degree \( z_1 \) and \( z_2 \) respectively, then \( P^{z_1}Q^{z_2} \) represents a non-zero element of \( E(\Lambda) \) if and only if the product of paths \( P^{z_1}Q^{z_2} \) in \( kQ \) is the underlying path of a maximal overlap sequence of degree \( z_1 + z_2 \). In this case \( P^{z_1}Q^{z_2} \) represents an element in \( E(\Lambda) \) of degree \( z_1 + z_2 \).

In particular, with this description we can avoid the lifting of maps usually associated to the Yoneda product. Therefore maximal overlap sequences are fundamental to the results presented in Chapter 2.
The definitions of the above paragraphs work for a general quiver $Q$ with monomial relations, but in this chapter and the next we restrict $Q$ to an oriented cycle. This is a special case where, given a $(z-1)$-chain $p$, there is at most one $z$-chain of the form $pr$. We can thus form a sequence of $z$-chains defined as follows. Let $v$ be the start vertex of some relation $r$, and for $z \geq 2$ let $A^z_v$ be the unique $(z-1)$-chain, if it exists, starting at $v$. Note that $A^z_v = r$. Then we say the sequence $A_v := (A^z_v)_{z \geq 2}$ is the extending sequence of $A$ starting at $v$. We define $o(A_v)$ as being the vertex $v$. The suffix will often be omitted if the start vertex itself is clear from the context or if it is unspecified. Thus $A_v$ is formed from the sequence of maximal overlaps

$A_v := (A^z_v)$

with $o(s_2) = v$ and $A^z_v$ being the maximal overlap sequence $(s_2, s_3, \ldots, s_2)$. We also define the lower half of $A_v$; this is the sequence of relations $(s_{2j})_{j \geq 1}$, where each $s_{2j}$ is the unique relation such that $t(s_{2j}) = t(A^2_v)$. The upper half of $A_v$ is the sequence of relations $(s_{2j+1})_{j \geq 1}$, where each $s_{2j+1}$ is the unique relation such that $t(s_{2j+1}) = t(A^{2j+1}_v)$. We may also define the maximum degree attained by $A_v$, denoted $\text{maxdeg } A_v$. If the sequence $A_v$ terminates at some degree $z \geq 2$ (that is $A^z_v$ is a $(z-1)$-chain but $A^{z+1}_v$ does not exist) then $\text{maxdeg } A_v = z$; it is defined as $\infty$ otherwise. Note that $\text{maxdeg } A_v$ must always be at least 2.

1.2 Monomial algebras and cycle algebras

Here we review the results that show the fundamentality of cycle algebras in the study of the Ext-algebra of a monomial algebra. We draw our material from [18] and from a discussion with the authors of [18] that took place in June 2004.

**Definition 1.2.1** [18] Let $B$ be a monomial algebra and let $Q$ be a quiver consisting of a single oriented cycle in the quiver $\Gamma$ of $B$. ($Q$ may be "larger" than $\Gamma$ since $Q$ is allowed to go through the same vertex or arrow more than once). Let $f : Q \rightarrow \Gamma$ be a map of quivers (i.e. $f$ sends vertices to vertices and arrows to arrows). We take the relations on $Q$ by pulling back the relations on $\Gamma$, i.e. a path in $Q$ is a relation if its image in $\Gamma$ is a relation in $B$. Let $Z_Q$ be the algebra with quiver $Q$ and with the above relations on $Q$. Then $Z_Q$ is said to be a cycle algebra overlying $B$. We say that $Z_Q$ is a minimal cycle algebra overlying $B$ if $Z_Q$ is not a finite covering of a smaller overlying cycle algebra.
Here we mean that, for oriented cycles $Q$ and $Q'$, $Z_{Q'}$ is a finite covering of $Z_Q$ if there is a surjective quiver map $Q' \to Q$ that takes relations to relations and each relation in $Q$ lifts to one in $Q'$.

The reason we consider minimal cycle algebras is due to the following result from [18]. As no proof was given in [18], for completeness we provide a more detailed proof here.

**Proposition 1.2.2** [18] Let $Q$ be the quiver of a minimal cycle algebra $Z_Q$ and let $Q'$ be the quiver of a cycle algebra $Z_{Q'}$ overlying $Z_Q$. Then $E(Z_{Q'})$ is finitely generated if and only if $E(Z_Q)$ is finitely generated.

**Proof.** Let $Q$ have $q$ vertices and $q$ arrows. Then there exists a positive integer $d$ such that $Q'$ has $dq$ vertices and $dq$ arrows.

Let $E(Z_Q)$ be finitely generated, with $b_1, \ldots, b_t$ a complete set of generators from our usual basis described in the previous section. Each $b_i$ in $E(Z_Q)$ lifts to one of $d$ different paths in $Q'$. Since the relations on $Q'$ are taken from $Q$ we get that each $b_i$ corresponds to a set of $d$ basis elements of $E(Z_{Q'})$, denoted $b'_i = \{b'_{i1}, \ldots, b'_{id}\}$.

We will now show that $E(Z_{Q'})$ is finitely generated with generating set $\bigcup_{i=1}^{t} b'_i$.

Let $a'$ be an element from the usual basis of $E(Z_{Q'})$. The underlying path in $Q'$ of $a'$ corresponds to a path $a$ in $Q$. Since the relations on $Q'$ are taken from $Q$ we have that $a$ is a basis element of $E(Z_Q)$. Write $a$ as a finite product of the $b_i$'s. For each copy of a generator that appears in this product there is a single natural choice $1 \leq j \leq d$ so that $a'$ is written as a non-zero product of the $b'_{ij}$'s. We can be certain of obtaining a non-zero product because the relations of $Q'$ are taken from $Q$. Since $a'$ was arbitrary, $E(Z_{Q'})$ is finitely generated.

Similarly, if we assume that $E(Z_{Q'})$ is finitely generated, then an arbitrary basis element $a$ in $E(Z_Q)$ corresponds to some $a'$ in $E(Z_{Q'})$, and thus it is shown that $E(Z_Q)$ is finitely generated. \qed

We now consider the following claim from [18].

**Claim 1.2.3** [18, Proposition 1.6] Let $B$ be a monomial algebra. Then the Ext-algebra $E(B)$ is finitely generated if and only if the $k$-algebras $E(Z_Q)$ are finitely generated for all minimal cycle algebras $Z_Q$ overlying $B$.

We give a proof for one direction stated in the following proposition.
Proposition 1.2.4 Let $B$ be a monomial algebra and let the Ext-algebra $E(B)$ be finitely generated. Then the $k$-algebras $E(Z_Q)$ are finitely generated for all minimal cycle algebras $Z_Q$ overlying $B$.

Proof. Let $B$ be a monomial algebra with quiver $\Gamma$ and let $E(B)$ be finitely generated with (basis) generators $b_1, \ldots, b_l$. Also let $Z_Q$ be an overlying minimal cycle algebra of $B$. Reordering if necessary, let $b_1, \ldots, b_k$ be precisely those generators of $E(B)$ whose underlying paths lie on the closed path in $\Gamma$ that is the image of $Q$. Since the relations of $Z_Q$ are lifted from $B$ we have that $b_1^*, \ldots, b_k^*$ are corresponding basis elements of $E(Z_Q)$.

Now let $a^*$ be a basis element of $E(Z_Q)$. Then we have $a$ as the corresponding basis element of $E(B)$, so $a$ can be written as a product of $b_1, \ldots, b_l$. However, if $b_i$ is a subpath of $a$ then $b_i^*$ is a path in $Q$, thus $a$ is a product of $b_1, \ldots, b_k$ and so $a^*$ is a product of $b_1^*, \ldots, b_k^*$.

Since $a^*$ was arbitrary we get that $E(Z_Q)$ is finitely generated. □

The details of the proof of this proposition are not given in [18]. Following discussion with the authors of [18], we state here that the reverse implication of the claim above is false. They have provided a counter-example which we give as Example 2.4.25 in Section 2.4, where we can treat it more fully.

However, it is the direction proved in Proposition 1.2.4 above that is most useful to us. With it, it is clear that finding just one overlying cycle algebra with infinitely generated Ext-algebra gives us the Ext-algebra of $B$ infinitely generated. Hence studying the Ext-algebras of cycle algebras is fundamental. Of course $B$ has finite global-dimension if its quiver has no oriented cycles: then $E(B)$ is trivially finitely generated.

We note here that a similar result exists for the respective Ext-algebras being Noetherian. In Section 2.5 we look at when the Ext-algebra of a cycle algebra is Noetherian, and Proposition 2.5.9 is the Noetherian analogue to Proposition 1.2.4.

This finishes our foundation chapter. In the next chapter we will see an efficient way to view the Ext-algebra of a cycle algebra, and subsequently how to use this to determine if the Ext-algebra is Noetherian, finitely generated or infinitely generated.
Chapter 2

Ext-algebra of cycle algebras

2.1 The smo-tube

For this chapter we turn exclusively to the study of the Ext-algebra of a monomial cycle algebra $\Lambda$, that is $\Lambda = kQ/I$, where $Q$ is an oriented cycle and $I$ has monomial generators. In this section we give the basic definition of the smo-tube and show how it relates to the extending sequences of $\Lambda$. We begin by giving some notation that will be used throughout the chapter.

If $v$ and $w$ are vertices let $v \rightarrow w$ denote the path in $kQ$ from $v$ to $w$ with length in the range 0 to $n - 1$ inclusive. The arrow will only ever be used with this precise meaning. Let $v$ be a vertex, $z$ some integer. Then $v + z$ is a vertex where the addition is integer addition modulo $n$. We identify the vertex $v$ with the trivial path $e_v$ in $kQ$ of length 0 at $v$. Let $p$ be a path in $kQ$. If $p \in kQ dkQ$ for some path $x$ of length 0 (or 1), then we say that $x$ is a vertex in $p$ (respectively arrow in $p$). Likewise if $p \in JxJ$, where $J$ is the 2-sided ideal of $kQ$ generated by the arrows, we say that $x$ is a vertex (respectively arrow) strictly in $p$.

Label the relations $r_1, \ldots, r_m$ such that the concatenation of $m$ paths $H_1 \rightarrow H_2 \rightarrow \cdots \rightarrow H_m \rightarrow H_1$ has length $n$, where $H_i = o(r_i)$. Likewise let $T_i = t(r_i)$. Here we work modulo $m$. We call $H_i$ the head vertex or head, and $T_i$ the tail vertex or tail of the relation $r_i$. An arrow is called a head arrow of $r_i$ if its start vertex is $H_i$. Let $\alpha_i$ be the head arrow of $r_i$, so $o(\alpha_i) = H_i$, and let $\omega_i$ be the arrow that ends at $T_i$, so $t(\omega_i) = T_i$. A head vertex $H$ is said to follow a tail vertex $T$ if the path $T \rightarrow H$ is of minimal length among all paths starting at $T$ and ending at a head vertex. If a tail vertex $T$ is also a head vertex $H$ then we also say $H$ follows $T$.

Our first results give us some control over the behaviour of maximal overlap sequences.
Proposition 2.1.1 Let \( A \) have \( m \) relations \( r_1, \ldots, r_m \) with the path \( H_1 \to \cdots \to H_m \to H_1 \) of length \( n \). Then the path \( T_1 \to \cdots \to T_m \to T_1 \) is also of length \( n \).

Proof. We will use induction on \( m \). For \( m = 1 \) or \( m = 2 \) the result is trivially true. Suppose then that \( m = 3 \) and that the three relations are such that \( H_1 \to H_2 \to H_3 \to H_1 \) is of length \( n \). Let \( r_i = \alpha_i \cdots \omega_i \), for \( 1 \leq i \leq 3 \). Note that we do not restrict the length of any of the \( r_i \). First write \( r_1 \) as a path and then write \( r_2 \) as a path underneath \( r_1 \) so that the first arrow in \( r_2, \alpha_2, \) lines up with the first occurrence of \( \alpha_2 \) in \( r_1 \):

\[
\begin{align*}
  r_1 &= \alpha_1 \cdots \omega_1 \\
  r_2 &= \alpha_2 \cdots \omega_2
\end{align*}
\]

Certainly the last arrow of \( r_2 \) must be to the right of the last arrow of \( r_1 \), otherwise \( r_2 \) would be a subpath of \( r_1 \). Also the last arrow of \( r_2 \) must in the diagram be less than \( n \) arrows to the right of the last arrow of \( r_1 \), or else \( r_1 \) would be a subpath of \( r_2 \). Thus the diagram above is the only case possible.

We note here that the above diagram may be misleading only in that we allow the relations to have length less than \( n \). In this case the two lengths marked "\( n \)" would overlap.

Now, to place \( r_3 \) in the diagram we use the same reasoning as above:

\[
\begin{align*}
  r_1 &= \alpha_1 \cdots \omega_1 \\
  r_2 &= \alpha_2 \cdots \omega_2 \\
  r_3 &= \alpha_3 \cdots \omega_3
\end{align*}
\]

that is, the last arrow of \( r_3 \) must be to the right of the last arrow of \( r_2 \), but less than \( n \) arrows to the right of the last arrow of \( r_1 \). We thus get that the path \( T_1 \to T_2 \to T_3 \to T_1 \) is of length \( n \).

For the inductive hypothesis suppose that if we have \( m - 1 \) relations with the path \( H_1 \to \cdots \to H_{m-1} \to H_1 \) of length \( n \), then the path \( T_1 \to \cdots \to T_{m-1} \to T_1 \) is of length \( n \).
For the inductive step suppose we have \( m \geq 4 \) relations \( r_1, \ldots, r_m \) with the path 
\( H_1 \rightarrow \cdots \rightarrow H_m \rightarrow H_1 \) of length \( n \). By considering the first \( m - 1 \) relations we use the inductive hypothesis and get a diagram:

\[
\begin{array}{c|c|c}
\alpha_1 & \cdots & \omega_1 \\
\alpha_2 & \cdots & \omega_2 \\
\vdots & & \vdots \\
\alpha_{m-1} & \cdots & \omega_{m-1} \\
\end{array}
\]

We now place \( r_m \) on the diagram as shown below. Note that, to avoid respectively \( r_m \) being a subpath of \( r_{m-1} \) or \( r_1 \) being a subpath of \( r_m \), the last arrow of \( r_m \) must be to the right of the last arrow of \( r_{m-1} \) but less than \( n \) arrows to the right of the last arrow of \( r_1 \).

\[
\begin{array}{c|c|c}
\alpha_1 & \cdots & \omega_1 \\
\alpha_2 & \cdots & \omega_2 \\
\vdots & & \vdots \\
\alpha_{m-1} & \cdots & \omega_{m-1} \\
\alpha_m & \cdots & \omega_m \\
\end{array}
\]

Hence by induction we get our result. \( \square \)

**Proposition 2.1.2** The path of unoverlapped arrows at the end of an odd-degree maximal overlap sequence always has length less than or equal to \( n \).

**Proof.** Let \( P^{2i+1} \) be an odd-degree maximal overlap sequence of degree \( 2i+1 \). The proof will proceed by induction on \( i \). First let \( i = 1 \). Then we have a maximal overlap sequence of the form

\[
P^3 = \begin{array}{c|c}
q & t_3 \\
\hline
\ell & p \\
\end{array}
\]

where \( \ell(q) \leq n \) by definition of \( P^3 \) being a maximal overlap sequence. If \( \ell(p) > n \) then \( t_2 \) would be a subpath of \( t_3 \). Since this cannot happen we get that \( \ell(p) \leq n \) as required.
Now suppose that $P^{2i+1}$ is a maximal overlap sequence such that $P^{2i-1}$ has its right-hand path of unoverlapped arrows ($ga$ in the diagram below) of length less than or equal to $n$.

We will show that the length of the path $ah$ cannot exceed $n$. First note that since $a$ is a (terminal) subpath of $ga$ we have $\ell(a) \leq \ell(ga) \leq n$. Thus if $\ell(ah) > n$ then $\ell(h) > 0$ and a copy of $\sigma_{2i}$ must lie in $h$. This is a contradiction since by maximality of the construction of $P^{2i+1}$ the path $h$ must be free from head arrows. Hence $\ell(ah) \leq n$. Therefore we must have $\ell(p) \leq n$ to avoid $s_{2i}$ being a subpath of $s_{2i+1}$.

**Lemma 2.1.3** Let $P^{2i}$ be a maximal overlap sequence of degree $2i$ with last relation $s_{2i}$. If $\ell(s_{2i}) > n$ then one can always overlap $P^{2i}$ on the right with another relation.

**Proof.** If $i = 1$ the result follows since a relation of length greater than $n$ has to overlap itself. For $i > 1$, $P^{2i}$ takes the form:

If there are $n$ or more unoverlapped arrows at the end of $P^{2i}$ then we are done, so set $p$ equal to the path of unoverlapped arrows and suppose $\ell(p) < n$; let $q$ be such that $s_{2i} = qp$. Now, since $\ell(s_{2i}) > n$ we must have at least two copies of the head arrow of $s_{2i}$ appearing in $s_{2i}$. By Proposition 2.1.2 only one copy can appear in $q$ and so we must have at least one copy in $p$. □

We will use the following two examples throughout the chapter to illustrate our method.

**Example 2.1.4** Let $Q$ be an oriented cycle with 25 vertices labelled 1, ..., 25. Label an arrow $\eta_i$ if it starts at vertex $i$. Let $\mathcal{I} = \langle r_1, r_2, r_3, r_4, r_5, r_6, r_7, r_8 \rangle$, where:

\[
\begin{align*}
    r_1 &= \eta_1 \cdots \eta_3, \quad r_2 = \eta_4 \cdots \eta_5, \quad r_3 = \eta_6 \cdots \eta_7, \quad r_4 = \eta_8 \cdots \eta_9, \\
    r_5 &= \eta_10 \cdots \eta_13, \quad r_6 = \eta_14 \cdots \eta_15, \quad r_7 = \eta_16 \cdots \eta_17, \quad r_8 = \eta_18 \cdots \eta_19.
\end{align*}
\]
with \( \ell(r) \leq n \), for all relations \( r \). Then let \( \Lambda = kQ/I \). We thus have head vertices \( H_1 = 1, H_2 = 7, H_3 = 8 \) etc, and tail vertices \( T_1 = 14, T_2 = 16, T_3 = 18 \), etc. The following diagram illustrates which vertices are head or tail vertices in our example.

Note that \( H_2 \) is the head vertex that follows \( T_6 \), and \( H_5 \) follows \( T_7, T_8 \) and \( T_1 \).

**Example 2.1.5** Let \( Q \) be an oriented cycle with 30 vertices labelled 1, \ldots, 30. Label an arrow \( \eta_i \) if it starts at vertex \( i \). Let \( I = \langle r_1, r_2, \ldots, r_{13} \rangle \), where:

- \( r_1 = \eta_1 \cdots \eta_{11} \), \( r_2 = \eta_3 \cdots \eta_{12} \), \( r_3 = \eta_6 \cdots \eta_{14} \), \( r_4 = \eta_7 \cdots \eta_{15} \), \( r_5 = \eta_9 \cdots \eta_{19} \),
- \( r_6 = \eta_{12} \cdots \eta_{20} \), \( r_7 = \eta_{14} \cdots \eta_{23} \), \( r_8 = \eta_{18} \cdots \eta_{25} \), \( r_9 = \eta_{19} \cdots \eta_{27} \), \( r_{10} = \eta_{22} \cdots \eta_{29} \),
- \( r_{11} = \eta_{25} \cdots \eta_3 \), \( r_{12} = \eta_{27} \cdots \eta_4 \), \( r_{13} = \eta_{29} \cdots \eta_7 \)

and where each relation \( r \) is such that \( n < \ell(r) \leq 2n \). Let \( \Lambda = kQ/I \). We thus have head vertices \( H_1 = 1, H_2 = 3, H_3 = 6 \) etc, and tail vertices \( T_1 = 12, T_2 = 13, T_3 = 15 \), etc. Note that \( H_2 \) does not follow any tail vertex, and \( H_8 \) follows \( T_3 \) and \( T_4 \). It is important for the reader to note that the number of vertices in \( Q \) and the spacing between head and tail vertices is unimportant. It is the relative positions of the head and tail vertices that matter.

**Definition 2.1.6** A *semi-maximal-overlap-sequence* or *smo-sequence* of a tail vertex \( T_i \) is a sequence of indices \( (a_1, a_2, \ldots) \) from the set \( X_m = \{1, \ldots, m\} \). It is defined inductively in the following way.

(i) \( a_1 = i \).

(ii) For \( k \geq 1 \), \( a_{k+1} = l \) where \( H_l \) is the head vertex that follows \( T_{a_k} \).
The *smo-function* of the algebra $\Lambda$, $f_\Lambda : X_m \rightarrow X_m$, is defined as $f_\Lambda(p) = q$, where $H_q$ is the head vertex that follows $T_p$. Thus $f$ moves us one place along an smo-sequence.

Since entries in an smo-sequence are taken from a finite set and an entry is dependent only on its direct predecessor, we have that after a certain stage the sequence will repeat.

**Definition 2.1.7** Let $(a_i)$ be an smo-sequence. Then a subsequence $(a_i, a_{i+1}, \ldots, a_{i+j-1})$ is a *repetition in $\Lambda$* if $j \geq 1$ is minimal such that $a_i = a_{i+j}$. The *order* of this repetition is $j$. If $a_k$ is a component of a repetition, i.e. $i \leq k \leq i+j-1$ as above, call $a_k$ a *repetition index* and $r_{a_k}$ a *repetition relation*. We say two repetitions are equal if they share a common component, that is they have respective components $a_k$ and $b_{k'}$ such that $a_k = b_{k'}$. It is clear that if two repetitions share one component in this way, they share all components. The *connective path* for repetition relations $r_{a_k}$ and $r_{a_{k+1}}$ is the path $T_{a_k} \rightarrow H_{a_{k+1}}$, denoted $c_{a_{k+1}}$. The connective paths of a repetition $R = (a_i, a_{i+1}, \ldots, a_{i+j-1})$ are the paths $c_{a_{i+1}}, c_{a_{i+2}}, \ldots, c_{a_{i+j}}$ and the connective paths of $\Lambda$ are those of all the repetitions of $\Lambda$. If $x$ is a component of $R$ then the head vertex $H_x$ is said to be $R$-indexed.

The lower half of an extending sequence starting at the vertex $H_{a_1}$ may be illustrated as below, with $a_1$ the first repetition index in the sequence $(a_k)$.

Note that no vertex of $Q$ can be in two distinct connective paths of $\Lambda$.

**Example 2.1.8** In Example 2.1.4 we have two distinct repetitions, each of order 2: $R_1 = (1,5)$ and $R_2 = (2,6)$. We have four connective paths, $\eta_{25}$ and $\epsilon_{14}$ associated with $R_1$, $\eta_{67}$ and $\eta_{16}\eta_{17}\eta_{8}\eta_{19}$ associated with $R_2$. The smo-sequences of $T_1$ and $T_2$ are $(1,5,1,5,\ldots)$ and $(2,6,2,6,\ldots)$ respectively.

**Example 2.1.9** In Example 2.1.5 we have two distinct repetitions, each of order 3: $R_1 = (1,6,10)$ and $R_2 = (3,8,12)$. We have six connective paths, $\eta_{30}$, $\epsilon_{12}$ and $\eta_{21}$ associated with $R_1$, $\eta_{5}$, $\eta_{15}\eta_{16}\eta_{17}$ and $\eta_{26}$ associated with $R_2$. The smo-sequences of $T_1$ and $T_3$ are $(1,6,10,1,6,10,\ldots)$ and $(3,8,12,3,8,12,\ldots)$ respectively.

**Lemma 2.1.10** All repetitions of $\Lambda$ are of the same order.
Proof. If $A$ has precisely one repetition, and this is of order 1, we are immediately done. We treat all other cases together. Thus let $R_x$ be a repetition of order $k$ with connective paths $c_{x_1}, c_{f_A(x_1)}, \ldots, c_{f_A^{k-1}(x_1)}$ and let $R_y$ be a repetition of order $l$ with connective paths $c_{y_1}, c_{f_A(y_1)}, \ldots, c_{f_A^{l-1}(y_1)}$. Recall that $f_A^k(x_1) = x_1$ and $f_A^l(y_1) = y_1$ and that $c_{x_1}$ is the path $T_{f_A^{k-1}(x_1)} \to H_{x_1}$ and $c_{y_1}$ is the path $T_{f_A^{l-1}(y_1)} \to H_{y_1}$. Relabelling if necessary, suppose that $c_{x_1}$ and $c_{y_1}$ are adjacent on the quiver, that is, they are the only distinct connective paths of $R_x$ and $R_y$ respectively that are subpaths of the path $T_{f_A^{k-1}(x_1)} \to H_{y_1}$. We will show that $c_{f_A(x_1)}$ and $c_{f_A(y_1)}$ are the only connective paths of $R_x$ and $R_y$ respectively that are subpaths of the path $T_{x_1} \to H_{f_A(y_1)}$.

Let $\sigma \subseteq \rho$ be the set of relations whose indices appear in $R_x$ or $R_y$. In particular the head vertex of each of these relations is the end vertex of a connective path of either $R_x$ or $R_y$. By hypothesis we have no head vertex indexed by a relation in $\sigma$ in the path $H_{x_1} \to H_{y_1}$ except the start and end vertices. Thus by Proposition 2.1.1 there is no tail vertex indexed by a relation in $\sigma$ in the path $T_{x_1} \to T_{y_1}$ except the start and end vertices. Hence $c_{f_A(x_1)}$ and $c_{f_A(y_1)}$ are the only connective paths of $R_x$ or $R_y$ that are subpaths of the path $T_{x_1} \to H_{f_A(y_1)}$. Inductively it follows that $k = l$, giving equality of the orders of $R_x$ and $R_y$. □

Remark 2.1.11 The above proof gives us some insight not present in the statement of the lemma: we will thus refer to the proof itself later in the chapter. In particular we note here a consequence. Suppose that $A$ has two or more repetitions, of order $\lambda$, and let $c_{x_1}$ and $c_{y_1}$ be any two distinct connective paths, with no other connective paths in the path $T_{f_A^{\lambda-1}(x_1)} \to H_{y_1}$. Then $c_{x_1}$ and $c_{y_1}$ are in different repetitions.

The reader may like to note that diagrams of the sort in the proof above can be drawn to illustrate most of the proofs in this chapter.
We now define the smo-tube (by first defining the smo-array), which is a combinatorial description of the maximal overlap sequences of \( \Lambda \).

**Definition 2.1.12** 1. A *degeneration path* is a path \( T_p \rightarrow H_q \), denoted \( d_q \), with no head or tail vertices strictly in the path \( d_q \) and such that, unless \( d_q \) is of zero length, \( o(d_q) \) is not a head vertex and \( t(d_q) \) is not a tail vertex. Then \( H_q \) follows \( T_p \) and we call \( T_p \) and \( H_q \) respectively *degeneration tail* and *head* vertices. Notice that every connective path has exactly one degeneration path as a terminal subpath: this means that every repetition index is also the index of a degeneration head vertex. Let \( D \) be the set of degeneration paths of \( \Lambda \), with elements labelled \( d_{q_1}, d_{q_2}, \ldots, d_{q_{|D|}} \) so that \( p_1 < p_2 < \cdots < p_{|D|} \) with respect to the ordering of the relations of \( \Lambda \), where \( T_{p_i} = o(d_{q_i}) \) for \( 1 \leq i \leq |D| \).

2. Place the smo-sequence of \( T_{p_i} \) in the \( i \)-th row of an array where row 1 is at the bottom. We call this array the *smo-array*.

In practice one need only write down the first \( L \) columns, for \( L = M + \lambda + 1 \), where the \( M \)-th column is the first to contain only repetition indices and \( \lambda \) is the order of the repetitions. We can bound the size of \( L \) as follows. Consider any row \( i \) in the smo-array that has entry \( (i, M - 1) \) not a repetition index. Since there are \( m \) relations, at least \( \lambda \) of which are repetition relations, we have \( M - 1 \leq m - \lambda \). This yields a bound of \( L = M + \lambda + 1 \leq m + 2 \). Since \( |D| \leq m \) we can have no more than \( m(m + 2) \) entries in the first \( L \) columns of the smo-array.

Fix the above definitions of \( \lambda, M \) and \( D \) for the remainder of the chapter. We consider the top row of the above array to be joined to the bottom, and so, once the flags of the next definition have been placed, we will call this array the *smo-tube* and denote it \( T_{\Lambda} \). In this spirit we will refer to the \( j \)-th column as *band* \( j \). Henceforth *entry* \((i, j)\) refers to the entry of the smo-tube (or array) in row \( i \), band \( j \). Thus if \((a_k)\) is an smo-sequence such that \( a_s = (i, j) \), for some \( s, i, j \), then \( a_{s+1} = (i, j + 1) \).

**Example 2.1.13** In Example 2.1.4 we have 5 degeneration paths: \( \eta_{25}, \eta_{37}, \epsilon_{14}, \eta_{18}\eta_{19} \) and \( \eta_{22} \). We thus have the smo-array:

\[
\begin{array}{cccccc}
1 & 2 & 3 & 4 & 5 & 6 \\
5 & 6 & 2 & 6 & 2 & 6 \\
4 & 5 & 1 & 5 & 1 & 5 \\
3 & 4 & 8 & 5 & 1 & 5 \\
2 & 3 & 6 & 2 & 6 & 2 \\
1 & 1 & 5 & 1 & 5 & 1 \\
\end{array}
\]
Here we have $M = 3$ and $\lambda = 2$, giving $L = 6$. Let us look again at extending sequences to see how they relate to the smo-array. The extending sequence $A_{H_1}$ has lower half $(r_1, r_5, r_3, r_5, \ldots)$ and upper half $(r_2, r_6, r_2, r_6, \ldots)$, yielding the overlaps

However, the extending sequence $A_{H_2}$ terminates almost immediately, that is at degree 3, with the maximal overlap sequence

It is clear that the reason for this degree 3 termination is that $T_2$ is not the start of a degeneration path. We also view the overlaps from which $A_{H_3}$ is formed:

Note that in all but position 1, the upper half of $A_{H_3}$ is the same as the lower half of $A_{H_5}$. This occurs because the same head vertex, $H_6$, follows $T_2$ and $T_3$.

**Example 2.1.14** In Example 2.1.5 we have 10 degeneration paths: $e_{12}, \eta_{13}, \eta_{16} \eta_{17}, \eta_{21}, \eta_{24}, \eta_{26}, \eta_{28}, \eta_{30}, \eta_5$ and $\eta_8$. We thus have the smo-array:

Here we have $M = 4$ and $\lambda = 3$, giving $L = 8$.

Example 2.1.13 well illustrates what happens for general $\Lambda$, inasmuch as two things go. Firstly, if $T_k$ is not a degeneration tail vertex then $A_{H_k}$ terminates at
degree 3. This is clear since if $T_k$ is not a degeneration tail vertex then it is immediate that we have no head arrows in the path $T_k \rightarrow T_{k+1}$. By Proposition 2.1.2 this path is equal to the path of unoverlapped arrows in the maximal overlap sequence

This maximal overlap sequence therefore cannot be overlapped by a relation on the right. Note that $r_k$ can always be overlapped by $r_{k+1}$ if $T_k$ is not a degeneration tail vertex. This is why we include only degeneration tail vertices in the first band of the smo-array: all other tail vertices give rise to extending sequences that terminate at degree 3.

Secondly, we have the following result.

**Lemma 2.1.15** Suppose that $T_a$ and $T_b$ are degeneration tail vertices. If $\Lambda$ has only one degeneration path take $T_a = T_b$, otherwise take $T_a$ and $T_b$ such that the path $T_a \rightarrow T_b$ is of positive length (so $T_a \neq T_b$) and contains no other degeneration tail vertices. Consider the upper-half of $A_{H_a}$, $(r_{a+1}, r_{f_a(a+1)}, r_{f_2(a+1)}, \ldots)$, and the lower-half of $A_{H_b}$, $(r_b, r_{f_a(b)}, r_{f_2(b)}, \ldots)$. Then $r_{f_k(a+1)} = r_{f_k(b)}$ for all $k \geq 1$.

**Proof.** If $\Lambda$ has only one degeneration path then this is immediate since $H_{f_a(b)}$ is the head vertex that follows all tail vertices, and thus follows $T_{a+1}$. So suppose $T_b$ is different from $T_a$, as above, and consider $T_{a+1}$. By hypothesis there cannot be a head vertex in the path $T_{a+1} \rightarrow T_b$, other than possibly $T_b$ itself, else we would have a degeneration tail vertex strictly in the path $T_a \rightarrow T_b$. Hence we have that $H_{f_a(b)}$ is the head vertex that follows both $T_{a+1}$ and $T_b$, giving $r_{f_a(a+1)} = r_{f_a(b)}$. It follows immediately that $r_{f_k(a+1)} = r_{f_k(b)}$ for all $k \geq 1$, and hence that the upper-half of $A_{H_a}$ is identical to the lower-half of $A_{H_b}$ in all places but the first. □

For this reason we include only the lower halves of extending sequences $A_{H_k}$, where $T_k$ is a degeneration tail vertex, as rows in the smo-array. We then get the upper halves automatically from the row above. This simplifies matters a great deal, as long as we keep track of what’s really happening in band 1.

The above reasoning has shown that the smo-array contains all the information needed to build the infinite extending sequences of $\Lambda$. However, with the smo-array as it stands, we are unable to tell which, if any, of the extending sequences terminate. The problem is that smo-sequences are infinite whilst extending sequences can be
finite, terminating in a maximal overlap sequence that cannot be overlapped on the right by a relation. We solve this problem by introducing flags to the smo-array. The position of a flag in some row $i$ of $T_A$ indicates that the extending sequence with lower half associated to row $i$ terminates; the exact point of termination depends on the type of flag. For an extending sequence $A_v$ of $A$, Theorem 2.1.19 gives the exact values of $\maxdeg(A_v)$ for each position and type of flag. The following definition gives the rules for marking the smo-array with the different types of flag. Recall that $\alpha_k$ is the first arrow of the relation $r_k$.

**Definition 2.1.16** 0. **Flags of type 0.** For $1 \leq i \leq |D|$, entry $(i,j)$ is marked flag0 if and only if $j = 1$, $\ell(r_{(i,1)}) \leq n$ and $r_{(i,1)}$ contains no head arrow other than $\alpha_{(i,1)}$.

1. **Flags of type 1.** If $|D| = 1$ then no entry is marked flag1.

If $|D| > 1$, then for $1 \leq i \leq |D|$ and $2 \leq j \leq l$, entry $(i,j)$ of the smo-tube is marked flag1 if and only if $(i,j) \neq (i+1,j)$ and no head arrow lies in the path $T(i,j) \rightarrow T(i+1,j)$. Note that if $i = |D|$ then $i+1 = 1$.

2. **Flags of type 2.** If $|D| = 1$ take $(2,1) = (1,1) + 1$, and $(2,j) = (1,j)$ for $j \geq 2$.

If $|D| > 1$ and $i = |D|$ then take $i+1 = 1$. Let $N(i,j)$ be the number of occurrences of $\alpha_{(1,1)}$ in $r_{(i,j)}$.

(i) For $2 \leq i \leq |D|$, $2 \leq j \leq l$, entry $(i,j)$ is marked flag2 if and only if $\sum_{k=1}^{j-1} N(i+1,k) = \sum_{k=1}^{j} N(i,k)$ and

* for $j = 2$ we have $(i,1) + 1 \neq (i,2)$ and no head arrow lies in the path $T(i,1) + 1 \rightarrow T(i,2)$,
* for $3 \leq j \leq l$ we have $(i,j) \neq (i+1,j-1)$ and no head arrow lies in the path $T(i+1,j-1) \rightarrow T(i,j)$.

(ii) Entry $(1,j)$, for $2 \leq j \leq l$, is marked flag2 if and only if $1 + \sum_{k=1}^{j-1} N(2,k) = \sum_{k=1}^{j} N(1,k)$ and

* for $j = 2$ we have $(1,1) + 1 \neq (1,2)$ and no head arrow lies in the path $T(1,1) + 1 \rightarrow T(1,2)$,
* for $3 \leq j \leq l$ we have $(1,j) \neq (2,j-1)$ and no head arrow lies in the path $T(2,j-1) \rightarrow T(1,j)$. 

21
Example 2.1.17 In Example 2.1.4 the only entry to be marked with a flag is entry $(3,2)$: it is a flag1. In Example 2.1.5 the entries marked with a flag are $(2,3), (5,2), (7,3)$ and $(10,2)$: they are all flag1s. We return to these examples in Section 2.2 with more detail.

The above definition is a very slow way to calculate flags and so Section 2.2 will present three theorems which speed up this calculation. However, we do have the following corollary of Lemma 2.1.3.

Corollary 2.1.18 If all relations $r$ are such that $\ell(r) > n$, then no flag0s or flag2s can be placed in the smo-tube.

We complete this section by proving that the flags defined in Definition 2.1.16 really do give us precisely the termination points of the finite extending sequences.

Theorem 2.1.19 Let $A$ be an extending sequence with $o(A) = H_a$ and let $T_A$ be the smo-tube of $A$. Then

1. $\text{maxdeg } A = 2$ if and only if $a = (i,1)$ for some row $i$ of $T_A$, and $(i,1)$ is marked flag0,
2. $\text{maxdeg } A = 3$ if and only if $a \neq (i,1)$ for all rows $i$,
3. $\text{maxdeg } A = 2j, \text{some } j \geq 2$, if and only if $a = (i,1)$ for some row $i$, and $(i,j)$ is marked flag2 and is the first flagged entry in row $i$,
4. $\text{maxdeg } A = 2j + 1, \text{some } j \geq 2$, if and only if $a = (i,1)$ for some row $i$, and $(i,j)$ is marked flag1 and is the first flagged entry in row $i$,
5. $\text{maxdeg } A = \infty$ if and only if $a = (i,1)$ for some unflagged row $i$.

Proof. Let us look in turn at the different ways in which an extending sequence might terminate.

(1) Let $A$ be an extending sequence; by definition $A$ attains at least degree 2. The degree 2 maximal overlap sequence is just a single relation, $r_k$ say. Thus by previous reasoning, $A$ terminating at degree 2 is equivalent to $k$ equalling $(i,1)$, for some row $i$ in $T_A$, and $r_k$ not having any relation overlapping it. This in turn is equivalent to $k$ equalling $(i,1)$, for some row $i$ in $T_A$, and $r_k$ containing no head arrows other than $\alpha_k$ once at the start: exactly the condition needed to mark entry $(i,1)$ with a flag0.
(2) We have seen already how $T_A$ excludes precisely those extending sequences that terminate at degree 3.

(3) Whether the extending sequence $A$ terminates at degree $2j$, for some $j \geq 2$, is, a priori, more difficult to determine. We know already that this condition is equivalent to the degree $2j$ maximal overlap sequence of $A$

\[ A^{2j} = \begin{array}{cccccc}
  s_2 & s_3 & s_4 & \ldots & s_{2j-1} & p \\
\end{array} \]

having no head arrows in the path of unoverlapped arrows $p$. The problem is that $p$ may have length less, greater or equal to $n$. If $\ell(p) \geq n$ then there will be a head arrow in $p$, and we can conclude that $A$ does not terminate at degree $2j$. If $\ell(p) < n$ then $p$ equals the path $t(s_{2j-1}) \rightarrow t(s_{2j})$. We then just need to check the path $t(s_{2j-1}) \rightarrow t(s_{2j})$ for head arrows to determine whether or not $A$ terminates at degree $2j$. We calculate whether $\ell(p) < n$ with a counting argument. Let $A^{2j}$ be the maximal overlap sequence shown above, with $o(A^{2j}) = o(s_2)$.

Suppose first that the lower half of $A^{2j}$ is not in row 1 of $T_A$. Consider the two paths in $kQ$ that consist of $A^{2j-1}$ and $A^{2j}$ with the path $a_L$ appended to the start of each, where $\ell(a_L) < n$, $o(a_L) = H_{(1,1)}$, $t(a_L) = o(s_2)$ and $a_U$ is the path as shown below.

Let $U = a_L A^{2j-1}$ and $L = a_L A^{2j}$. We visualise the paths $U$ and $L$ respectively in the following natural way.

\[ U = c^k q, \] where $c$ is the cycle such that $\ell(c) = n$, $o(c) = t(c) = H_{(1,1)}$ and $q$ is such that $\ell(q) < n$, $o(q) = H_{(1,1)}$, $t(q) = t(s_{2j-1})$. Then $L = U p = c^k q p$. We will count the number of occurrences of $\alpha_{(1,1)}$ in $U$ and in $L$. Then, if $\alpha_{(1,1)}$ occurs more
often in $L$ than in $U$, we can conclude that at least one $\alpha_{(1,1)}$ is in $p$. Since $\alpha_{(1,1)}$ is a head arrow we would know that $A$ does not terminate at degree $2j$. Otherwise, if $\alpha_{(1,1)}$ occurs the same number of times in $U$ as it does in $L$ then we know it cannot occur in $p$. Thus $\ell(p) < n$ and so we check the path $t(s_{2j-1}) \rightarrow t(s_{2j})$ for head arrows as detailed above.

For any finite path $\nu \in kQ$ let $N(\nu)$ be the number of occurrences of $\alpha_{(1,1)}$ in $\nu$. Then $N(L) = 1 + \sum_{i=1}^{j} N(s_{2i})$ and $N(U) = 1 + \sum_{i=2}^{j} N(s_{2i-1})$. For firstly the “gaps” between the relations (the paths $Y_z$, $4 \leq z \leq 2j$, in the Preliminaries section) contain no head arrows by maximality of the construction of $A^{2j}$, and secondly, since $\alpha(s_2) \neq H_{(1,1)}$ the paths $a_U$ and $a_L$ contain exactly one copy of $\alpha_{(1,1)}$. Thus $\sum_{i=1}^{j} N(s_{2i}) = \sum_{i=2}^{j} N(s_{2i-1}) \Leftrightarrow N(L) = N(U) \Rightarrow \ell(p) < n$; and $\sum_{i=1}^{j} N(s_{2i}) > \sum_{i=2}^{j} N(s_{2i-1}) \Leftrightarrow N(L) > N(U) \Rightarrow p$ contains a head arrow. Note that the function $N$ here is an extension to all paths of the function of the same name in Definition 2.1.16. By Lemma 2.1.15 it remains to see that $N(s_2) = N(i+1,1)$, where $s_2 = r_{(i,1)}$. If $s_3 = r_{(i+1,1)}$ this is immediate, so suppose they are different. Now, the same head vertex follows $t(s_3)$ and $T_{(i+1,1)}$, and since $T_{(i+1,1)}$ is the start of a degeneration path we get the following diagram, which is not necessarily a maximal overlap sequence itself, but where we do minimise the length of the left-hand path of unoverlapped arrows.

Note that the right-hand path of unoverlapped arrows does not contain a head arrow. If the left-hand path of unoverlapped arrows contained $\alpha_{(1,1)}$ then, since $t(s_3)$ does not start a degeneration path, the right-hand path of unoverlapped arrows would contain $\omega_{(1,1)}$. Since $T_{(1,1)}$ is the start vertex of a degeneration path we must have $\alpha_{(1,2)}$ in the right-hand path of unoverlapped arrows. This cannot happen. Hence neither path of unoverlapped arrows contains $\alpha_{(1,1)}$, giving us $N(s_3) = N(i+1,1)$.

This shows that marking entry $(i,j)$ with a flag $2$ via Definition 2.1.16, part 2(i), is equivalent to the corresponding maximal overlap sequence terminating at degree $2j$.

The case where $\alpha(s_2) = H_{(1,1)}$ is almost identical to above; the only change is that now $\ell(a_L) = 0$ and we have $N(a_L) = 0$, $N(a_U) = 1$. This is left to the reader.
(4) This part follows part 3 above, but without the necessity for the counting argument, since by Proposition 2.1.2 the path of unoverlapped arrows \( p \) is always such that \( \ell(p) \leq n \).

(5) It is clear that there are only three ways an extending sequence can terminate: if its first relation cannot be overlapped on the right, or if it contains a maximal overlap sequence of either odd or even degree greater than or equal to 3 that has no head arrows in its right-hand path of unoverlapped arrows. We have shown that the presence of each of the three types of flag in \( T_A \) is equivalent to a termination, in one of the above ways, of the associated extending sequence. Hence a row without flags corresponds to an extending sequence \( A \) that does not terminate, that is \( \maxdeg A = \infty \). □

2.2 Calculating Flags

In this section we present three theorems that speed up calculation of the smo-tube with its flags: for this reason the section becomes rather technical. Note that certain of the auxiliary results presented here will be drawn upon throughout the remainder of the chapter. We will illustrate calculation of the smo-tube with two examples.

**Lemma 2.2.1** For any entry \((i, j)\) in an smo-tube, we have that the concatenation of paths \( H_{(i,j)} \to H_{(i+1,j)} \to \cdots \to H_{(j,|D|,j)} \to H_{(1,j)} \to \cdots \to H_{(i-1,j)} \to H_{(i,j)} \) is of length \( n \).

**Proof.** Using Proposition 2.1.1 and the discussion in Definition 2.1.12, the result follows by induction on \( j \). □

**Lemma 2.2.2** If \( x \) is some repetition index, then for all \( j \) greater or equal to 2, there exists some row \( i \) in \( T_A \) such that \( x = (i, j) \).

**Proof.** Recall that band 1 contains the indices of all degeneration tail vertices. By definition the next entry in the smo-sequence of a such a tail vertex is the index of a degeneration head. We get all degeneration head indices this way; these appear in band 2. As remarked in Definition 2.1.12, each repetition index is also a degeneration head index, and so each repetition index appears in band 2. Immediately we get that each repetition index appears in band \( j \), for all \( j \geq 2 \). □
Theorem 2.2.3 If an entry \((i,j)\) of \(T_A\) is assigned a flag1 then \((i,j) \neq (i+1,j)\) and \((i,j+1) = (i+1,j+1)\).

Moreover, if \(A\) has more than one repetition index then \((i,j)\) is assigned a flag1 if and only if \((i,j) \neq (i+1,j)\) and \((i,j+1) = (i+1,j+1)\).

**Proof.** If entry \((i,j)\) is marked with a flag1 then by definition \((i+1,j) \neq (i,j)\) and there is no head arrow in the path \(T_{(i,j)} \rightarrow T_{(i+1,j)}\). This means that \(H_{(i,j+1)}\) follows both \(T_{(i,j)}\) and \(T_{(i+1,j)}\) giving \(H_{(i,j+1)} = H_{(i+1,j+1)}\) and so \((i,j+1) = (i+1,j+1)\).

Conversely suppose that \((i,j)\) is such that \((i,j) \neq (i+1,j)\) and \((i,j+1) = (i+1,j+1)\); this means that either the path \(T_{(i,j)} \rightarrow T_{(i+1,j)}\) or the path \(T_{(i+1,j)} \rightarrow T_{(i,j)}\) is free from head arrows. Suppose also that \(A\) has more than one repetition index. By Lemma 2.2.2 all repetition indices occur in band \(j+1\) so, since \(A\) has more than one repetition index, there must be a third row in \(T_A\), row \(k\) say, such that \((i+1,j+1) \neq (k,j+1)\). This gives us \((i+1,j) \neq (k,j)\) and \((i,j) \neq (k,j)\). Thus we have that \(T_{(i,j)} \rightarrow T_{(i+1,j)} \rightarrow T_{(k,j)} \rightarrow T_{(i,j)}\) is a path of length \(n\) by Lemma 2.2.1 and Proposition 2.1.1. Since a different head vertex follows \(T_{(k,j)}\) than follows \(T_{(i,j)}\) and \(T_{(i+1,j)}\), there is a head vertex, namely \(H_{(k,j+1)}\), in the path \(T_{(i+1,j)} \rightarrow T_{(i,j)}\). Thus there must no head arrow in the path \(T_{(i,j)} \rightarrow T_{(i+1,j)}\), and so \((i,j)\) will be assigned a flag1.

**Proposition 2.2.4** The number of rows in \(T_A\) that do not have a flag1 is equal to the number of distinct repetition indices of \(A\).

**Proof.** Recall that the \(M\)-th band of \(T_A\) is the first to contain only repetition indices. If \(A\) has \(\mu \geq 2\) repetition indices then by Lemma 2.2.2 there must be some row \(i\) such that \((i,M+1) \neq (i+1,M+1)\). By Lemma 2.1.10 we get \((i,j) \neq (i+1,j)\), \(\forall j \geq 1\). Thus by Theorem 2.2.3, row \(i\) will never be marked flag1. Lemmas 2.2.1 and 2.2.2 give us exactly \(\mu\) rows \(i\) in \(T_A\) such that \((i,M+1) \neq (i+1,M+1)\), which gives us at least \(\mu\) rows without a flag1 by above. By Theorem 2.2.3, any row \(i\) with \((i,M+1) = (i+1,M+1)\) has a flag1. This gives us precisely the same number of unflagged rows as we have repetition indices.

Suppose then that \(A\) has only one repetition index. We get our result immediately if \(|D| = 1\), so suppose \(|D| \geq 2\). All entries of band \(M\) are equal to the same repetition index, \(x\) say. From the proof of Lemma 2.2.2, band 2 contains at least 2 distinct indices and so we have \(M \geq 3\). Now, all entries of band \(M-1\) index tail vertices that are followed by \(H_x\), so by Lemma 2.2.1 and Proposition 2.1.1 there
exists exactly one row, \( i \) say, such that the path \( T_{(i,M-1)} \rightarrow T_{(i+1,M-1)} \) contains a head arrow. It follows from Theorem 2.2.3 that row \( i \) will not get a flag1. Let row \( k \) be different to row \( i \). Then there exists \( j \), with \( 1 \leq j \leq M - 1 \), such that \( (k,j) \neq (k+1,j) \) and \( (k,j+1) = (k+1,j+1) \). We will show \((k,j)\) is marked flag1. To seek a contradiction suppose it is not. Then by definition, \( T_{(k,j)} \rightarrow T_{(k+1,j)} \) contains a head arrow. Since both \( T_{(k,j)} \) and \( T_{(k+1,j)} \) are followed by \( H_{(k,j+1)} \), this means the path \( T_{(k+1,j)} \rightarrow T_{(k,j)} \) must contain no head arrows. Hence by Lemma 2.2.1 we must have \( j = M - 1 \), but since \( k \neq i \), we get a contradiction. Thus entry \((k,j)\) is marked flag1 for all \( k \neq i \).

**Theorem 2.2.5** If entry \((i,1)\) of \( T_{\lambda} \) is marked flag0 then \((i,1) + 1 = (i,2) \) modulo \( m \).

Moreover, if \( \ell(r_{(i,1)}) \leq n \), entry \((i,1)\) is marked flag0 if and only if \((i,1) + 1 = (i,2) \) modulo \( m \).

**Proof.** Suppose \((i,1)\) is marked flag0. This means no head arrow lies in \( r_{(i,1)} \) except \( \alpha_{(i,1)} \) once at the start. Therefore \( H_{(i,1)+1} \) is the head vertex that follows \( T_{(i,1)} \), and hence \((i,1) + 1 = (i,2) \).

Conversely, suppose \((i,1) + 1 = (i,2) \) and that \( \ell(r_{(i,1)}) \leq n \). We have that \( H_{(i,1)+1} \) is the head vertex that follows \( T_{(i,1)} \) and so the path \( H_{(i,1)} \rightarrow T_{(i,1)} \rightarrow H_{(i,1)+1} \) must have length less than or equal to \( n \). Suppose \( r_{(i,1)} \) is not the only relation, else we are done. This means \((i,1) \neq (i,1) + 1 \) and so \( \alpha_{(i,1)} \) is the only head arrow in the path \( H_{(i,1)} \rightarrow H_{(i,1)+1} \). Since \( \ell(r_{(i,1)}) \leq n \), \( r_{(i,1)} \) must be an initial subpath of \( H_{(i,1)} \rightarrow H_{(i,1)+1} \). Thus \( r_{(i,1)} \) contains no head arrow other than \( \alpha_{(i,1)} \). Hence \((i,1)\) gets marked with a flag0. □

To prove a similar theorem concerning flag2s we need access to a few more results. Recall that \( \lambda \) is the order of the repetitions.

**Proposition 2.2.6** If \( \lambda \geq 2 \), and \( r_{x_1} \) and \( r_{x_2} \) are two distinct relations, then the path \( H_{x_1} \rightarrow T_{x_1} \rightarrow T_{x_2} \rightarrow H_{x_2} \rightarrow H_{x_1} \) has length greater than \( n \).

**Proof.** We proceed by contradiction. Assume that \( r_{x_1} \) and \( r_{x_2} \) are distinct relations such that the path \( H_{x_1} \rightarrow T_{x_1} \rightarrow T_{x_2} \rightarrow H_{x_2} \rightarrow H_{x_1} \) is of length \( n \). Since \( \lambda \geq 2 \), \( H_{x_2} \) cannot follow \( T_{x_2} \). We therefore have a third relation, \( r_{x_3} \) say, distinct from \( r_{x_1} \) and \( r_{x_2} \), such that \( H_{x_3} \) is in the path \( T_{x_2} \rightarrow H_{x_2} \rightarrow 1 \). By Proposition 2.1.1, \( T_{x_3} \) must lie in the path \( T_{x_1} \rightarrow T_{x_2} \).

It is clear that each time this argument is applied to \( r_{x_i} \) and \( r_{x_i} \), for some \( i \geq 2 \), we get a new relation \( r_{x_{i+1}} \) distinct from all the others. Since \( I \) has a fixed finite generating set, we get our contradiction. □
Corollary 2.2.7 Suppose \( \lambda \geq 2 \) and let \( r_k \) be a relation such that \( cn < \ell(r_k) \leq (c+1)n \), for some non-negative integer \( c \). Then \( cn < \ell(r) \leq (c+1)n \) for all relations \( r \).

**Proof.** Let \( r_k \) be a relation such that \( cn < \ell(r_k) \leq (c+1)n \), for some positive integer \( c \) and let \( r_i \) be a relation such that \( (c-1)n < \ell(r_i) \leq cn \). To ensure that \( r_i \) is not a subpath of \( r_k \) it is clear that the path \( H_k \to T_k \to T_i \to H_t \to H_k \) must have length \( n \). This contradicts the above proposition. \( \square \)

**Definition 2.2.8** Let \( r_{y_1}, \ldots, r_{y_l} \) be the repetition relations of \( A \), ordered such that the concatenation of \( l \) paths \( H_{y_1} \to H_{y_2} \to \cdots \to H_{y_l} \to H_{y_1} \) is of length \( n \). Then we call the path \( H_{y_i} \to H_{y_{i+1}} \) the repetition path \( b_{y_{i+1}} \), where \( l + 1 = 1 \). Clearly every arrow in \( kQ \) is in precisely one repetition path.

**Example 2.2.9** In Example 2.1.4 the repetition relations are \( r_1, r_2, r_5 \) and \( r_6 \); the repetition paths are \( \eta_1 \cdots \eta_6, \eta_7 \cdots \eta_{13}, \eta_{14} \cdots \eta_{19} \) and \( \eta_{20} \cdots \eta_{25} \).

In Example 2.1.5 the repetition relations are \( r_1, r_3, r_6, r_8, r_{10} \) and \( r_{12} \); the repetition paths are \( \eta_1 \cdots \eta_5, \eta_6 \cdots \eta_{11}, \eta_{12} \cdots \eta_{17}, \eta_{18} \cdots \eta_{21}, \eta_{22} \cdots \eta_{26} \) and \( \eta_{27} \cdots \eta_{30} \).

**Lemma 2.2.10** Suppose \( \lambda \geq 2 \). Let \( H_i \) be a degeneration head vertex with \( r_i \) not a repetition relation, and let \( H_i \) and \( T_i \) lie in the repetition path \( b_o \), with \( T_i \neq o(b_o) \). Then \( t(b_o) = H_a \) is the head vertex that follows \( T_i \).

**Proof.** Let the set-up be as above and let \( H_k = o(b_o) \), so that \( b_o \) is the path \( H_k \to H_a \). To seek a contradiction suppose \( H_a \) does not follow \( T_i \). Firstly, \( T_i \) lies in the path \( H_k + 1 \to H_l - 1 \) otherwise the path \( H_l \to T_i \to H_k \to H_k \to H_l \) would have length \( n \), since \( T_k \) is a repetition tail vertex. This would contradict Proposition 2.2.6. Now \( \lambda \geq 2 \), so \( H_a \) may not follow \( T_o \) and so \( T_o \), since it is a repetition tail vertex, is in the path \( H_o \to H_k \). By the ordering imposed by Proposition 2.1.1 we get that the path \( H_o \to T_a \to T_k \to H_k \to H_a \) is of length \( n \). This contradicts Proposition 2.2.6 and we get our result. \( \square \)

**Lemma 2.2.11** Suppose \( \lambda \geq 2 \) and let \((i, j)\) be an entry of \( T_A \). Then

1. if \( j = 2 \) the path \( H_{(i,1)} \to H_{(i,1)+1} \to H_{(i,2)} \to H_{(i+1,2)} \to H_{(i,1)} \) has length \( n \),

2. if \( j \geq 3 \) the path \( H_{(i,j-1)} \to H_{(i+1,j-1)} \to H_{(i,j)} \to H_{(i+1,j)} \to H_{(i,j-1)} \) has length \( n \).
**Proof.** (1) Suppose that \( j = 2 \). Since \( H_{(i,2)} \) and \( H_{(i+1,2)} \) are both degeneration head vertices, the path \( T_{(i,1)} \rightarrow H_{(i,2)} \rightarrow T_{(i,1)}+1 \rightarrow H_{(i+1,2)} \rightarrow T_{(i,1)} \) is of length \( n \). Also \( T_{(i+1,2)} \) must be in the path \( H_{(i+1,2)}+1 \rightarrow T_{(i,1)} \) since \( \lambda \geq 2 \). Now, \( T_{(i,2)} \) must be in the path \( T_{(i,1)} \rightarrow T_{(i+1,2)} \) else we contradict Proposition 2.2.6 with \( r_{(i+1,2)} \) and \( r_{(i,2)} \). Since \( \lambda \geq 2 \), \( T_{(i,2)} \neq T_{(i,1)} \) so in fact \( T_{(i,2)} \) is in the path \( T_{(i,1)}+1 \rightarrow T_{(i+1,2)} \). Thus the path \( T_{(i,1)} \rightarrow T_{(i,1)}+1 \rightarrow T_{(i,2)} \rightarrow T_{(i+1,2)} \rightarrow T_{(i,1)} \) has length \( n \) and Proposition 2.1.1 yields our result.

(2) Suppose now that \( j \geq 3 \). We show that the path \( H_{(i,j-1)} \rightarrow H_{(i+1,j-1)} \rightarrow H_{(i,j)} \rightarrow H_{(i+1,j)} \rightarrow H_{(i,j-1)} \) has length \( n \). Note that if \( (i, j-1) = (i+1, j-1) \) then \( (i, j) = (i+1, j) \) and we immediately get our result. Thus we assume \( (i, j-1) \neq (i+1, j-1) \). Consider the two vertices \( H_{(i,j-1)} \) and \( H_{(i+1,j-1)} \), the terminating vertices of the degeneration paths \( d_{(i,j-1)} \) and \( d_{(i+1,j-1)} \) respectively.

We first wish to place \( H_{(i,j)} \) in the path \( H_{(i+1,j-1)} \rightarrow H_{(i,j-1)} \). We assume \( (i, j) \neq (i+1, j-1) \) and \( (i, j) \neq (i, j-1) \). To seek a contradiction suppose \( H_{(i,j)} \) is in the path \( H_{(i,j)}+1 \rightarrow H_{(i+1,j-1)}-1 \). Then by Lemmas 2.2.1 and 2.2.2, \( d_{(i,j)} \), and therefore \( d_{(i,j-1)} \), cannot be a repetition degeneration path. By Lemma 2.2.10 this means \( H_{(i,j)} \) and \( H_{(i,j-1)} \) cannot be in the same repetition path. Thus there must be a repetition head vertex in the path \( H_{(i,j)}+1 \rightarrow H_{(i,j)}-1 \), contradicting Lemmas 2.2.1 and 2.2.2 regarding band \( j-1 \). Hence \( H_{(i,j)} \) must lie in the path \( H_{(i+1,j-1)} \rightarrow H_{(i,j-1)}-1 \).

It remains only to locate \( H_{(i+1,j)} \) in the path \( H_{(i,j)} \rightarrow H_{(i,j-1)} \). Assume \( (i+1, j) \neq (i,j) \) and \( (i+1, j) \neq (i, j-1) \). There are two cases to consider.

(i) If \( H_{(i+1,j)} \) lies in the path \( H_{(i,j-1)} \rightarrow H_{(i+1,j-1)} \) then so does \( T_{(i+1,j-1)} \). Two sub-cases arise. If \( H_{(i+1,j-1)} \) is a repetition head then so is \( H_{(i+1,j)} \). This is contradicted by Lemmas 2.2.1 and 2.2.2. If \( H_{(i+1,j-1)} \) is not a repetition head then we must have a repetition head in the path \( H_{(i+1,j)} \rightarrow H_{(i+1,j-1)} \) or Lemma 2.2.10 will be contradicted. However, the existence of this repetition head again contradicts Lemmas 2.2.1 and 2.2.2.

(ii) If \( H_{(i+1,j)} \) lies in the path \( H_{(i,j)}+1 \rightarrow H_{(i,j)}-1 \) then so does \( T_{(i+1,j-1)} \). Proposition 2.2.6 on relations \( r_{(i,j-1)} \) and \( r_{(i+1,j-1)} \) provides the contradiction. \( \square \)

Hence \( H_{(i+1,j)} \) must lie in the path \( H_{(i,j)} \rightarrow H_{(i,j-1)} \). This completes the proof.

We can at last prove our final theorem of this section.
Theorem 2.2.12 If an entry \((i,j)\) of \(T_\lambda\) is assigned a flag2 then

1. for \(j = 2\) we have \((i,1) + 1 \neq (i,2)\) and \((i+1,2) = (i,3)\),
2. for \(j \geq 3\) we have \((i+1,j-1) \neq (i,j)\) and \((i+1,j) = (i,j+1)\).

Moreover, if \(\lambda \geq 2\) and \(\ell(r) \leq n\) for all relations \(r\), then \((i,j)\) is assigned a flag2 if and only if the appropriate condition 1. or 2. holds.

Proof. If \((i,j)\) is assigned a flag2 then showing the appropriate condition 1. or 2. is easy.

For the reverse direction, suppose \(\lambda \geq 2\) and \(\ell(r) \leq n\) for all relations \(r\). Suppose also that \(j \geq 3\) and the conditions from 2. hold. For a contradiction assume that no flag2 is assigned to entry \((i,j)\). As \(\ell(r) \leq n\) for all relations \(r\), and by Theorem 2.1.19, no flag2 assigned to entry \((i,j)\) is equivalent to the existence of a head arrow in the path of unoverlapped arrows \(T_{(i+1,j-1)} \rightarrow T_{(i,j)}\). However, since \(T_{(i+1,j-1)}\) and \(T_{(i,j)}\) are both followed by the same head vertex, we have the path \(T_{(i,j)} \rightarrow T_{(i+1,j-1)}\) free from head arrows. As \(\lambda \geq 2\) we must have \(T_{(i+1,j)}\) in the path \(T_{(i+1,j-1)} + 1 \rightarrow T_{(i,j)} - 1\). This means the path \(T_{(i+1,j-1)} \rightarrow T_{(i,j)} \rightarrow T_{(i+1,j)}\) has length greater than \(n\), contradicting Lemma 2.2.11.

The case of \(j = 2\) is similar. \(\square\)

Example 2.2.13 For our algebra of Example 2.1.4, we have a single flag1 in the smo-tube. There are no flag0s or flag2s. The position of the flag1 is indicated by the square box.

```
1 2 3 4 5 6 ····
5 6 2 6 2 6 2 ····
4 5 1 5 1 5 1 ····
3 4 8 5 1 5 1 ····
2 3 6 2 6 2 6 ····
1 5 1 5 1 5 ····
```

Theorem 2.2.3 was used to mark the flag1: notice above that \((3,2) \neq (4,2)\) but that \((3,3) = (4,3)\). Since here \(\ell(r) \leq n\) for all relations \(r\), and \(\lambda \geq 2\) we may use the full equivalences of Theorems 2.2.5 and 2.2.12 to conclude that there are no flag0s or flag2s present in \(T_\lambda\).
Example 2.2.14 For our algebra of Example 2.1.5, we have four flag1s in the smo-tube. Again there are no flag0s or flag2s.

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
10 & 13 & 5 & 10 & 1 & 6 & 10 & 1 & 6 \\
9 & 12 & 3 & 8 & 12 & 3 & 8 & 12 & 3 \\
8 & 10 & 1 & 6 & 10 & 1 & 6 & 10 & 1 \\
7 & 9 & 13 & 5 & 10 & 1 & 6 & 10 & 1 \\
6 & 8 & 12 & 3 & 8 & 12 & 3 & 8 & 12 \\
5 & 7 & 11 & 3 & 8 & 12 & 3 & 8 & 12 \\
4 & 6 & 10 & 1 & 6 & 10 & 1 & 6 & 10 \\
3 & 4 & 8 & 12 & 3 & 8 & 12 & 3 & 8 \\
2 & 2 & 7 & 11 & 3 & 8 & 12 & 3 & 8 \\
1 & 1 & 6 & 10 & 1 & 6 & 10 & 1 & 6
\end{array}
\]

Since here \(\ell(r) > n\), for all relations \(r\), we may not use the full equivalences of Theorems 2.2.5 and 2.2.12. However, this smo-tube still has the respective conditions required to conclude that there are no flag0s or flag2s present.

Example 2.2.15 Let us consider a different example. We keep the same quiver of 25 vertices and 25 arrows, but this time put on 6 relations:

\[
\begin{align*}
r_1 &= \eta_1 \cdots \eta_6, & r_2 &= \eta_2 \cdots \eta_{10}, & r_3 &= \eta_4 \cdots \eta_{13}, \\
r_4 &= \eta_0 \cdots \eta_{15}, & r_5 &= \eta_{15} \cdots \eta_{22}, & r_6 &= \eta_{18} \cdots \eta_{24}.
\end{align*}
\]

We get a different smo-tube; this time all rows have a flag. The position of a flag0 or flag2 is indicated by a circle; the flag1 by the square.

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 \\
4 & 6 & 1 & 4 & 6 & 1 & 4 & 6 \\
3 & 4 & 6 & 1 & 4 & 6 & 1 \\
2 & 3 & 5 & 1 & 4 & 6 & 1 \\
1 & 1 & 4 & 6 & 1 & 4 & 6 & 1
\end{array}
\]

Notice in each example that the number of rows without a flag1 is equal to the number of repetition indices, as stated in Proposition 2.2.4. It is no fluke that all the rows have flags in the second example above. The next section, while introducing the notion of shifts, shows that if an smo-tube has any flag0s or flag2s at all, then all rows have a flag.

31
2.3 Repetition shift

The aim of this section is to present some further structure of the smo-tube, the so-called repetition shift, and we see how important the repetition shift is in governing the placement of flags. This importance is shown in Theorem 2.3.14, which gives exact conditions for when and how the different types of flag will be present on the smo-tube. We begin with a definition. Recall that the $M$-th band of $\mathcal{T}_\Lambda$ is the first to contain only repetition indices and that $f_\Lambda$ is the smo-function of $\Lambda$.

**Definition 2.3.1** Let $a$ and $b$ be rows in $\mathcal{T}_\Lambda$ that share the same repetition. Then row $a$ is said to have a $b$-shift of $N$ if $(a, M + N) = (b, M)$ and $N > 0$ is minimal with this property.

**Lemma 2.3.2** Let $R$ be a repetition of $\Lambda$ with order $\lambda \geq 2$. Let $x_1, \ldots, x_\lambda$ be the repetition indices of $R$ with the path $H_{x_1} \rightarrow \cdots \rightarrow H_{x_k} \rightarrow H_{x_1}$ of length $n$. If $N > 0$ is minimal such that $f_\Lambda^N(x_1) = x_2$, then $N$ is minimal such that $f_\Lambda^N(x_i) = x_{i+1}$, for all $i = 1, \ldots, \lambda$. Note that if $i = \lambda$ we take $i + 1 = 1$.

**Proof.** Pick $2 \leq k \leq \lambda$. Let $l$ be minimal such that $f_\Lambda^l(x_1) = x_k$. Thus $f_\Lambda^{l+N}(x_1) = f_\Lambda^l(x_k)$ giving $f_\Lambda^{l+N}(x_2) = f_\Lambda^N(x_k)$. Now the proof of Lemma 2.1.10, applied $l$ times, gives us no $R$-indexed head vertex in the path $H_{f_\Lambda^l(x_1)} \rightarrow H_{f_\Lambda^l(x_2)}$ except the start and end vertices. Hence there is no $R$-indexed head vertex in the path $H_{x_k} \rightarrow H_{f_\Lambda(x_2)}$ except the start and end vertices. Thus $f_\Lambda^l(x_2) = x_{k+1}$, and so $f_\Lambda^N(x_k) = x_{k+1}$. Minimality of $N$ follows since $x_1$ was arbitrary. $\square$

Motivated by this result, we now make the following definition.

**Definition 2.3.3** Let $R$ be a repetition of $\Lambda$, with $x_1$ and $x_2$ repetition indices of $R$ such that no $R$-indexed head vertex lies in the path $H_{x_1} \rightarrow H_{x_2}$ except the start and end vertices. The repetition shift of $R$ is the least positive integer $N$ such that $f_\Lambda^N(x_1) = x_2$.

**Example 2.3.4** We take the usual oriented cycle $Q$ with 25 vertices and 25 arrows, and let $\Lambda = kQ/I$, where $I$ is generated by the 8 relations:

- $r_1 = \eta_1 \cdots \eta_6$,
- $r_2 = \eta_3 \cdots \eta_9$,
- $r_3 = \eta_5 \cdots \eta_{21}$,
- $r_4 = \eta_8 \cdots \eta_{22}$,
- $r_5 = \eta_{12} \cdots \eta_{24}$,
- $r_6 = \eta_{14} \cdots \eta_{4}$,
- $r_7 = \eta_{19} \cdots \eta_{11}$,
- $r_8 = \eta_{21} \cdots \eta_{14}$.
The only flags on this smo-tube are flag1s:

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & \\
5 & 7 & 5 & 1 & 7 & 5 & 1 & 7 \\
4 & 6 & 3 & 1 & 7 & 5 & 1 & 7 \\
3 & 5 & 1 & 7 & 5 & 1 & 7 & 5 \\
2 & 2 & 8 & 7 & 5 & 1 & 7 & 5 \\
1 & 1 & 7 & 5 & 1 & 7 & 5 & 1 \\
\end{array}
\]

There is only one repetition here, \( R = (1, 7, 5) \). The repetition shift \( N \) of \( R \) is equal to 2.

The repetition shift can be observed in the smo-tube by taking a flag1-free row containing \( R \): the \( b \)-shift of that row gives the repetition shift, where row \( b \) is the next flag1-free row up that contains \( R \).

**Example 2.3.5** The algebras in Examples 2.1.4 and 2.1.5 both have a repetition shift of \( N = 1 \).

**Lemma 2.3.6** Let \( \Lambda \) have a repetition with repetition shift \( N \). Then all repetitions of \( \Lambda \) have repetition shift \( N \).

**Proof.** If \( \Lambda \) has only one repetition we are done, so let \( R_x \) and \( R_y \) be two distinct repetitions of \( \Lambda \) with \( x_1, \ldots, x_\lambda \) and \( y_1, \ldots, y_\lambda \) the respective repetition indices of \( R_x \) and \( R_y \), ordered so that the paths \( H_{x_1} \to \cdots \to H_{x_\lambda} \to H_{y_1} \to \cdots \to H_{y_\lambda} \) have length \( n \). Also let \( R_x \) have repetition shift \( N \). Relabelling if necessary, let \( c_{f\lambda(x_1)} = T_{x_1} \to H_{f\lambda(x_1)} \) and \( c_{f\lambda(y_1)} = T_{y_1} \to H_{f\lambda(y_1)} \) be connective paths of \( R_x \) and \( R_y \) respectively, so that the only connective paths of \( \Lambda \) that lie in the path \( T_{x_1} \to H_{f\lambda(y_1)} \) are \( c_{f\lambda(x_1)} \) and \( c_{f\lambda(y_1)} \) themselves. By definition \( c_{f\lambda(x_1)} = c_{x_2} \) and so by the proof of Lemma 2.1.10, \( c_{f\lambda(x_1)} = c_{y_2} \). Hence \( R_y \) has repetition shift \( N \). This process can be iterated to show that all repetitions have repetition shift \( N \). \( \square \)

For the remainder of the chapter, fix \( N \) as the repetition shift of all the repetitions of \( \Lambda \).

**Proposition 2.3.7** Suppose \( \Lambda \) has only one repetition \( R \), and this is of order \( \lambda \geq 2 \). Then for each \( i \), row \( i \) of the smo-tube of \( \Lambda \) has \((i + 1)\)-shift equal to 0 or \( N \).
Proof. If we have only 2 degeneration paths then, since \( \lambda \geq 2 \), the indices of both paths must be repetition indices. So clearly \( R \) has a repetition shift of \( N = 1 \). Now, since there are only 2 rows in \( T_\lambda \), we get immediately from Lemma 2.2.2 that each row \( i \) has \((i + 1)\)-shift of 1.

Thus assume \( \Lambda \) has at least 3 degeneration paths. Let \( x_1, \ldots, x_\lambda \) be the repetition indices of \( R \), with the path \( H_{x_1} \rightarrow \cdots \rightarrow H_{x_\lambda} \rightarrow H_{z_1} \) of length \( n \). Let \( y \) and \( z \) be distinct degeneration head indices such that no degeneration head vertices lie in the path \( H_y \rightarrow H_z \) other than the start and end vertices. Then for some \( k \in \{1, \ldots, \lambda\} \) (with \( \lambda + 1 = 1 \)) we have that \( H_y \) and \( H_z \) lie in the path \( H_{x_k} \rightarrow H_{x_{k+1}} \). We will show that either \( f^M_n(y) = f^M_n(z) \) or \( f^M_n+y(z) = f^M_n(z) \).

By applying Proposition 2.1.1 \( M \) times we get that the path \( H_{f^M_n(x_k)} \rightarrow H_{f^M_n(y)} \rightarrow H_{f^M_n(z)} \rightarrow H_{f^M_n(x_{k+1})} \) has length less than or equal to \( n \). By \( M \) applications of the proof of Lemma 2.1.10 we have no repetition head vertices in this path except the start and end vertices. Since by the definition of \( M \), \( f^M_n(y) \) and \( f^M_n(z) \) are repetition indices, three possibilities occur:

1. \( f^M_n(y) = f^M_n(z) = f^M_n(x_k) \),
2. \( f^M_n(y) = f^M_n(z) = f^M_n(x_{k+1}) \),
3. \( f^M_n(y) = f^M_n(x_k), \quad f^M_n(z) = f^M_n(x_{k+1}) \).

Let \( i \) be such that \( y = (i, 2) \), and so by hypothesis \( z = (i + 1, 2) \). If either possibility (1) or (2) occurs then row \( i \) has an \((i + 1)\)-shift of 0, since \((i, M + 2) = f^M_n(y) = f^M_n(z) = (i + 1, M + 2) \) and hence \((i, M + \lambda) = (i + 1, M + \lambda) \), so \((i, M) = (i + 1, M) \). If possibility (3) occurs then \( f^M_n+y(z) = f^M_n(x_k) = f^M_n(x_{k+1}) = f^M_n(z) \), and by a similar argument \((i, M + N) = (i + 1, M) \); so row \( i \) has an \((i + 1)\)-shift of \( N \). \( \square \)

We can bring the above results together to form the next proposition, which builds upon Proposition 2.2.4. First though we have the following result.

Lemma 2.3.8 There is an ordering on the repetitions of \( \Lambda \): \( R_1, \ldots, R_l \) such that whenever \((i, j) \neq (i+1, j)\), for some \( j \geq M \), we have \((i, j) \in R_k \) and \((i+1, j) \in R_{k+1} \), some \( k \in \{1, \ldots, l\} \) with \( l + 1 = 1 \).
Proof. Let $\Lambda$ have smo-tube $T_\Lambda$ and $l$ repetitions of order $\lambda$ and let $(i, j)$ be an element of $T_\Lambda$, where $j \geq M$, and such that $(i, j) \neq (i + 1, j)$. From Lemma 2.2.1 we have that the path $H(i, j) \rightarrow H(i+1, j) \rightarrow \ldots \rightarrow H(j, j) \rightarrow H(1, j) \rightarrow \ldots \rightarrow H(i-1, j) \rightarrow H(i, j)$ is of length $n$. Now, since $j \geq M$ we have that each head vertex above is a repetition head vertex and moreover that, by Lemma 2.2.2, every repetition head vertex of $\Lambda$ is in this list. Therefore, since $(i, j) \neq (i + 1, j)$, we have two distinct connective paths $c_{(i, j)}$ and $c_{(i+1, j)}$ with no other connective paths in the path $\sigma(c_{(i, j)}) \rightarrow t(c_{(i+1, j)})$. Define the index $(i, j)$ to be in repetition $R_k$, for some $k \in \{1, \ldots, l\}$ with $l + 1 = 1$, and the index $(i + 1, j)$ to be in repetition $R_{k+1}$. By the proof of Lemma 2.1.10 every $R_k$-indexed connective path $c$ is followed on the quiver by a $R_{k+1}$-indexed connective path $c'$, that is $c'$ is such that the only connective paths that are subpaths of the path $\sigma(c) \rightarrow t(c')$ are $c$ and $c'$ themselves. Continuing in this way for each entry in band $j$ of $T_\Lambda$ yields our required order on the repetitions. □

Remark 2.3.9 Notice that in the case of Example 2.3.4 we have only one repetition. This renders Lemma 2.3.8 somewhat trivial in that $l = 1$, giving an ordered list of one element. Thus $R_{k+1} = R_k$ and the lemma is then obvious in this case.

Proposition 2.3.10 Suppose $\lambda \geq 2$. If the following conditions all occur:

1. $\Lambda$ has only one repetition $R$,

2. $R$ has repetition shift $N = 1$,

3. $\ell(r) \leq n$ for all relations $r$,

then all rows in $T_\Lambda$ are flagged.

Otherwise the number of unflagged rows is equal to the number of distinct repetition indices.

Proof. If conditions (1) and (2) hold then by Proposition 2.3.7, for each $i$, row $i$ has $(i+1)$-shift either 0 or 1. If this shift is 0 then, since $\lambda \geq 2$, we can use Theorem 2.2.3 to get a flag1 in row $i$. If the $(i+1)$-shift is 1 then by condition (3) we can use Theorems 2.2.5 and 2.2.12 to get a flag0 or flag2 in row $i$. Hence all the rows are flagged.

Otherwise Proposition 2.2.4 states there are the same number of rows without a flag1 as there are repetition indices. Thus we need to show there are no flag0s or flag2s in $T_\Lambda$ whenever one of the three conditions above fails.
If condition (1) fails we have 2 or more repetitions. Let \((i, j)\) be an entry of \(T_A\), with \(j \geq 3\). Suppose for a contradiction that \((i, j) = (i + 1, j - 1)\); then we have 
\((i, j + M) = (i + 1, j + M - 1)\) and so, since \(\lambda \geq 2\), this gives \((i, j + M) \neq (i + 1, j + M)\) with \((i, j + M)\) and \((i + 1, j + M)\) in the same repetition. This is prohibited by Lemma 2.3.8. We can thus assume that \((i, j) \neq (i + 1, j - 1)\) for all \(i, j\), and so by Theorem 2.2.12 we have no flag2s. A similar argument in the case \(j = 2\) shows that 
\((i, 2) \neq (i + 1, 1) + 1\) and hence by Theorem 2.2.5 that there are no flag0s.

If condition (2) fails then for all \(i\) and for all \(j \geq 3\) we have 
\((i, j) \neq (i + 1, j - 1)\) and \((i, 2) \neq (i + 1, 1) + 1\). Theorems 2.2.5 and 2.2.12 then give us no flag0s or flag2s.

If condition (3) fails we get our result by Corollaries 2.2.7 and 2.1.18. □

We now focus our attention to the case where the order of the repetitions is 1.

**Lemma 2.3.11** Let \(\lambda = 1\) and let \(r_x\) be a repetition relation. If \((a - 1)n < \ell(r_x) \leq an\) for some positive integer \(a\), then \((a - 1)n < \ell(r_k) \leq (a + 1)n\) for all relations \(r_k\).

**Proof.** Let \(a \in \mathbb{Z}\) be such that \((a - 1)n < \ell(r_x) \leq an\) and let \(r_k\) be some relation. Clearly we must have \(\ell(r_k) \leq (a + 1)n\) else \(r_x\) would be a subpath of \(r_k\).

Now, since \(H_x\) must follow \(T_x\), we must have \(H_k\) in the path \(H_x \rightarrow T_x\). The following three diagrams show the possible relative positions of \(T_k\): note that we allow \(T_1 = H_x\) and \(T_k = H_x\) or \(T_1 = H_x\) where appropriate. By looking at each diagram in turn it is not hard to see that we must have \(\ell(r_k) > (a - 1)n\) to prevent \(r_k\) being a subpath of \(r_x\).

![Diagrams showing relative positions of \(T_k\)]

**Corollary 2.3.12** Let \(\lambda = 1\) and let \(r_x\) and \(r_y\) be a repetition relations. If \((a - 1)n < \ell(r_x) \leq an\) for some positive integer \(a\), then \((a - 1)n < \ell(r_y) \leq an\).

**Proposition 2.3.13** Suppose \(\lambda = 1\). If the following conditions both occur:

1. \(\Lambda\) has only one repetition relation \(r_x\),
2. \(\ell(r_x) \leq n\),

36
then all rows in $T_A$ are flagged.

Otherwise the number of unflagged rows is equal to the number of distinct repetition indices.

**Proof.** Suppose both conditions hold and yet we have an unflagged row in the smo-tube of $A$. This gives rise to a degree $2M + 1$ maximal overlap sequence ending with

$$
\ldots \quad r_x \quad r_x
$$

which contradicts condition (2), since the head arrow of $r_x$ appears here in $r_x$ twice.

For the converse we will show that if either condition (1) or (2) fails then the number of unflagged rows in $T_A$ is equal to the number of repetition indices.

Suppose (1) fails. Then we have $k \geq 2$ repetition relations. We know from Proposition 2.2.4 that there are $k$ rows in $T_A$ with no flag1: let row $i$ be one of these. To seek a contradiction suppose that entry $(i, j)$ has a flag2 and that $j \geq 3$.

By Theorem 2.2.12 we have $(i, j) \neq (i + 1, j - 1)$ and $(i, j + 1) = (i + 1, j)$. Thus $(i, j + M + 1) = (i + 1, j + M)$ and so, since $\lambda = 1$, $(i, j + M + 1) = (i + 1, j + M + 1)$.

By Theorem 2.2.3 row $i$ has a flag1, contradicting our hypothesis. The cases where $j = 1$ or 2 are similar to the above, with the case $j = 1$ prohibiting flag0s.

Finally, if (2) fails then Lemma 2.3.11 and Corollary 2.1.18 show that there are no flag0s or flag2s in $T_A$. Thus by Proposition 2.2.4, the number of unflagged rows is equal to the number of distinct repetition indices. □

Putting the last two propositions together gives us the theorem of this section. Using Theorem 2.1.19 we follow with a useful corollary.

**Theorem 2.3.14** The smo-tube $T_A$ has every row flagged if and only if one of the following occurs:

1. $\lambda \geq 2$, there is only 1 repetition, $N = 1$, and $\ell(r) \leq n$ for all relations $r$.

2. $\lambda = 1$, there is only 1 repetition relation $r_x$, and $\ell(r_x) \leq n$.

Otherwise the smo-tube has the same number of unflagged rows as it does distinct repetition indices.

**Corollary 2.3.15** If $A$ has an infinite extending sequence, then $T_A$ has no flag0s or flag2s.

37
2.4 Finite generation of the Ext-algebra

The previous sections have given us a method to identify exactly those extending sequences that are infinite in extent. In this section we bring together these results to determine precisely when \( E(\Lambda) \) is finitely generated: Theorem 2.4.17, our main result, does this for us. Toward the end of this section there are a number of propositions each of which, for different conditions on \( E(\Lambda) \), give an explicit finite generating set. As noted in the Chapter 1, we will freely interchange a maximal overlap sequence and its underlying path. However, when we talk about products of maximal overlap sequences, we refer to the corresponding product as basis elements in \( E(\Lambda) \). Thus the product of two maximal overlap sequences may be zero in \( E(\Lambda) \), whilst the product of their underlying paths may be non-zero in \( kQ \). We recall here that, for \( \Lambda \) a cycle algebra, \( \lambda \) is the order of the repetitions, \( N \) is the repetition shift, and \( M \) is the first band of \( \mathcal{T}_\Lambda \) to contain only repetition indices.

Our first three results, for certain conditions on \( \Lambda \), give us restrictions on the behaviour of the maximal overlap sequences. These results will aid us when determining finite generation of \( E(\Lambda) \).

Lemma 2.4.1  (1) If \( \lambda \geq 2 \) and \( \ell(r) > n \) for all relations \( r \), then there are always \( n \) or more unoverlapped arrows at the end of any even-degree maximal overlap sequence.

(2) If \( \lambda = 1 \), \( r_x \) and \( r_y \) are repetition relations, and \( \ell(r) > n \) for all repetition relations \( r \), then there are always \( n \) or more unoverlapped arrows at the end of any even-degree maximal overlap sequence which ends

\[
\cdots \quad \begin{array}{c} \scriptstyle r_y \\ \hline \hline \scriptstyle r_x \end{array} \quad \begin{array}{c} \scriptstyle r_x \\ \hline \hline \scriptstyle r_x \end{array}
\]

Proof. (1) If the degree of the maximal overlap sequence is 2 then it is a relation and there is nothing to prove. Thus suppose the degree is \( \geq 4 \). If \( \ell(r) > 2n \) for all relations \( r \) the result is immediate using Proposition 2.1.2. So by Corollary 2.2.7 we may suppose \( n < \ell(r) \leq 2n \), for all relations \( r \). Let

\[
\cdots \quad \begin{array}{c} \scriptstyle r_j \\ \hline \hline \scriptstyle r_i \end{array} \quad \begin{array}{c} \scriptstyle r_i \\ \hline \hline \scriptstyle r_k \end{array}
\]
be the end of the even-degree maximal overlap sequence. Note that $r_i \neq r_k$ by hypothesis. If $r_j = r_k$ then the result is immediate, so assume $r_j \neq r_k$. By Theorems 2.2.3 and 2.1.19 we may assume $r_i \neq r_j$. The diagram below is a copy of the one above, but with the relative positions of certain arrows marked; the order in which an arrow has been marked is indicated below that arrow. Recall that for a relation $r_i$ we have $\alpha_i$ as the start arrow and $\omega_i$ as the end arrow.

Once the start and end arrows of each relation have been marked on the diagram above, we know we can mark the other arrows for the following reasons, given by order of marking.

Note that from Lemma 2.2.11 and Proposition 2.1.1 the paths $H_i \rightarrow H_j \rightarrow H_k \rightarrow H_i$ and $T_i \rightarrow T_j \rightarrow T_k \rightarrow T_i$ each have length $n$.

1. As $\ell(r_i) > n$, $r_i$ contains two copies of $\alpha_i$. One copy must lie in the overlapped part of $r_i$ and $r_j$, by Proposition 2.1.2 if the degree of the maximal overlap sequence is greater than or equal to 6, or trivially if the degree is 4. By the same reasoning a copy of $\alpha_k$ must lie in the unoverlapped part of $r_j$. We remark that $\alpha_i \neq \omega_i$ since a copy of $\alpha_j$ must lie between $\alpha_i$ and $\alpha_k$, but cannot lie in the path $g$. At this stage we allow the possibility that $\alpha_k = \omega_k$.

2. By the note above, a copy of $\alpha_k$ lies in $r_i$ between $\alpha_j$ and the copy of $\alpha_i$ placed in 1.

3. $H_k$ is the head vertex that follows $T_i$ by maximality of the overlap sequence, so $\omega_i$ sits as marked in the overlapped part of $r_i$ and $r_j$.

4. Three copies of $\omega_i$ cannot lie in $r_j$, but a copy of $\omega_i$ must lie in $r_k$, since $n < \ell(r_j), \ell(r_k) \leq 2n$. Thus there is a copy of $\omega_i$ as shown.

5. By the note above, a copy of $\omega_k$ lies in $r_k$ between $\omega_j$ and $\omega_i$.

The presence of two copies of $\omega_k$ in the unoverlapped part of $r_k$ yields our result.

(2) If the degree of the maximal overlap sequence is 2 then it is a relation and there is nothing to prove. Thus suppose the degree is $\geq 4$. If $\ell(r) > 2n$ for all relations $r$ the result is immediate using Proposition 2.1.2. So by Corollary 2.3.12 we may suppose $n < \ell(r) \leq 2n$, for all repetition relations $r$. Let
be the end of the even-degree maximal overlap sequence. Note that if \( r_x = r_y \) then the result is immediate, so assume \( r_x \neq r_y \). The diagram below is a copy of the one above, but with the relative positions of certain arrows marked; the order in which an arrow has been marked is indicated below that arrow. Recall that for a relation \( r_l \) we have \( \alpha_l \) as the start arrow and \( \omega_l \) as the end arrow.

\[
\begin{array}{c|c|c}
\alpha_x & \alpha_y & \omega_x \\
\hline
\alpha_y & \omega_y & \omega_z \\
\hline
\end{array}
\]

1. As \( \ell(r_x) > n \), \( r_x \) contains two copies of \( \alpha_x \). One copy must lie in the unoverlapped part of the second \( r_x \) by Proposition 2.1.2.

2. Since \( \lambda = 1 \), \( H_y \) is the head vertex which follows \( T_y \). This means a copy of \( \alpha_y \) is located between \( \omega_y \) and \( \alpha_x \), as shown.

3. Similarly, since \( \lambda = 1 \), \( H_x \) is the head vertex which follows \( T_x \). This means a copy of \( \omega_x \) is located between \( \alpha_y \) and \( \alpha_x \), as depicted.

The presence of two copies of \( \omega_x \) in the unoverlapped part of \( r_x \) yields our result. \( \square \)

**Proposition 2.4.2** A maximal overlap sequence \( P^{2k} \), \( k \geq 2 \), cannot be written as a product of maximal overlap sequences \( P^{2a+1} F^{2l+1} Q^b \), some \( a \geq 0 \), \( l \geq M + 1 \), \( b \geq 0 \), if one of the following occurs:

1. \( \lambda \geq 2 \), \( \lambda \) has \( \geq 3 \) repetitions,
2. \( \lambda \geq 2 \), \( \lambda \) has 2 repetitions and \( N \neq 1 \),
3. \( \lambda \geq 2 \), \( \lambda \) has only 1 repetition and \( 2N \neq 1 \) (mod \( \lambda \)),
4. \( \lambda \geq 2 \), \( \ell(r) > n \) for all relations \( r \),
5. \( \lambda = 1 \), \( \lambda \) has 2 repetition relations \( r_x \) and \( r_y \), and \( \ell(r_x), \ell(r_y) > n \),
6. \( \lambda = 1 \), \( \lambda \) has \( \geq 3 \) repetitions.

**Proof.** If \( P^{2k} \) is to be written as such a product, we at least need the product in \( kQ \) of the three underlying paths to be non-zero: thus we assume this now. Suppose for a contradiction that \( P^{2k} \) can be written as the above product. Consider the underlying path of \( F^{2l+1} \), represented thus

\[
\begin{array}{c|c|c}
P_{2a+1+3} & P_{2a+5} & \cdots \\
\hline
P_{2a+1} & \cdots & P_{2a+2l+1} \\
\hline
P_{2a+2l} & P_{2a+2l+2} \\
\end{array}
\]
where the relations are from $P^{2k}$, in the same positions that they appear in the corresponding part of the underlying path of $P^{2k}$.

Let us also construct $F^{2l+1}$ as a maximal overlap sequence, starting at $o(p_{2a+3})$:

Now look at $T_A$. If $p_{2a+2l+1} = p_{2a+2l+2}$ then two cases arise. Either $s_3 = p_{2a+3}$, in which case $p_{2a+3}$ is the only relation of $\Lambda$ by maximality of the overlap sequence, or $s_3 \neq p_{2a+3}$, in which case by Theorems 2.2.3 and 2.1.19 there is no such maximal overlap sequence of degree $2l + 1$. Both cases give a contradiction to the hypothesis.

So assume $p_{2a+2l+1} \neq p_{2a+2l+2}$. Let $f$, $g$ and $h$ be integers such that $1 \leq f, g, h \leq m$ and $r_f = p_{2a+2l+1}$, $r_g = p_{2a+2l+1}$ and $r_h = p_{2a+2l+2}$.

The two diagrams above, along with Lemmas 2.2.1 and 2.2.2, mean that we have part of the smo-tube taking the form

(1) By the remark following Lemma 2.1.10 the two indices $g$ and $h$ are in different repetitions, respectively $R_t$ and $R_s$ say. By Lemma 2.3.8 we have a special ordering on the repetitions, which says that $R_t$ follows $R_s$. However, since the index $f$ is in $R_s$ we have that $R_t$ follows $R_s$. Since there are more than two repetitions this contradicts Lemma 2.3.8. Hence $P^{2k}$ cannot be written as such a product.

(2) By the remark following Lemma 2.1.10 the two indices $g$ and $h$ are in the two different repetitions, respectively $R_t$ and $R_s$ say. However this means, using the index $g$ in the part of the smo-tube at (†), that the repetition shift is equal to 1. This contradicts the hypothesis.

(3) Here $f$, $g$ and $h$ are all in the one repetition. Using the index $g$ in the part of the smo-tube displayed at (†) we see that the twice the repetition shift is equal to 1 (mod $\lambda$). This contradicts the hypothesis.

(4) Let $F^{2l}$ be the maximal overlap sequence of degree $2l$ that has underlying path an initial subpath of the underlying path of $F^{2l+1}$. Then $F^{2l}$ can be viewed as
the maximal overlap sequence $F^{2l+1}$ above, but with the relation $p_{2a+2l+2}$ missing. By Lemma 2.1.2 we have $\ell(F^{2l+1}) < \ell(F^{2l}) + n$. However, consider the maximal overlap sequence $p^{2a+2l+2} = P^{2a+1}F^{2l+1}$. By Lemma 2.4.1 the right-hand path of unoverlapped arrows has length greater or equal to $n$. This gives us $\ell(F^{2l+1}) \geq \ell(F^{2l}) + n$, a contradiction.

(5) As in (4), let $F^{2l}$ be the maximal overlap sequence of degree $2l$ that has underlying path an initial subpath of the underlying path of $F^{2l+1}$. By Lemma 2.1.2 we have $\ell(F^{2l+1}) < \ell(F^{2l}) + n$. However, consider the maximal overlap sequence $p^{2a+2l+2} = P^{2a+1}F^{2l+1}$. By Lemma 2.4.1 the right-hand path of unoverlapped arrows has length greater or equal to $n$. This gives us $\ell(F^{2l+1}) \geq \ell(F^{2l}) + n$, a contradiction.

(6) This is identical to (1). □

**Lemma 2.4.3** Let $A$ be such that $\ell(r) \leq n$ for all repetition relations $r$ and suppose one of the following occurs:

1. $\lambda \geq 2$, $A$ has precisely 2 repetitions, $N = 1$,
2. $\lambda \geq 2$, $A$ has only 1 repetition, $2N \equiv 1 \pmod{\lambda}$,
3. $\lambda = 1$, $A$ has precisely 2 repetition relations.

Let $P^k$ be a maximal overlap sequence and let $S$ be the subpath (but not necessarily a maximal overlap sequence):

\[
\begin{array}{cccccc}
P_{2a+3} & P_{2a+5} & \cdots & P_{2a+2l-1} & P_{2a+2l+1} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
P_{2a+4} & \cdots & P_{2a+2l-2} & P_{2a+2l} & P_{2a+2l+2}
\end{array}
\]

for some $l \geq M$. The relations above are from $P^k$, in the same positions that they appear in the corresponding part of the underlying path of $P^k$. Then the path $S$ can be constructed as a maximal overlap sequence if and only if a maximal overlap sequence exists starting at $o(p_{2a+3})$ of degree $2l + 1$.

**Proof.** If the path $S$ can be formed as a maximal overlap sequence then it must take the form:

\[
\begin{array}{cccc}
x & x & \cdots & x \\
\vdots & \vdots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \vdots \\
x & x & \cdots & x
\end{array}
\]
which is a maximal overlap sequence of degree $2l + 1$.

We now prove the converse. Suppose there exists a maximal overlap sequence of degree $2l + 1$ starting at $a(p_{2a+3})$. It will take the form:

\[
\begin{array}{c}
\vline & \vline & \vline \\
\hline
s_3 & \cdots & s_{2l+1} \\
\hline
p_{2a+3} & p_{2a+2l-1} & p_{2a+2l+1}
\end{array}
\]

Since $\ell(r) \leq n$ for all relations $r$, it is enough to show that $s_{2l+1} = p_{2a+2l+2}$. It is clear that $s_{2l+1} \neq p_{2a+2l+1}$ and $p_{2a+2l+2} \neq p_{2a+2l+1}$. We now consider each case separately.

1. In $T_\lambda$, having 2 repetitions and $N = 1$ is equivalent to having $(i, j) = (i + 2 + k(i), j - 1)$ for every unflagged row $i$ and for $j \geq M$, where $k(i)$ is the number of flagged rows counting up from row $i$ to the next but one unflagged row. Consider band $a + l$ of $T_\lambda$. From the maximal overlap sequence $P^k$, and using Lemma 2.2.1, we can see this means that the index of $p_{2a+2l+2}$ is the next different one in band $a + l$ up from the index of $p_{2a+2l+1}$. Since $s_{2l+1} \neq p_{2a+2l+1}$ we thus get that $s_{2l+1} = p_{2a+2l+2}$.

2. In $T_\lambda$, $2N \equiv 1 \pmod{\lambda}$ is equivalent to having $(i, j) = (i + 2 + k(i), j - 1)$ for every unflagged row $i$ and for $j \geq M$, where $k(i)$ is the number of flagged rows counting up from row $i$ to the next but one unflagged row. The argument now follows that of (1).

3. In $T_\lambda$, having 2 repetitions and $\lambda = 1$ is equivalent to having $(i, j) = (i + 2 + k(i), j - 1)$ for every unflagged row $i$ and for $j \geq M$, where $k(i)$ is the number of flagged rows counting up from row $i$ to the next but one unflagged row. The argument now follows that of (1).

The following definition and proposition are fundamental to the finite generation of $E(\Lambda)$.

**Definition 2.4.4** Let $e_v$ be a zero-length connective path of some repetition $R$. For ease of notation, we write $R = (a_1, a_2, \ldots, a_\lambda)$ and $c_{a_i} = e_v$, with $o(r_{a_i}) = t(r_{a_\lambda}) = v$ and $f^v_{a_i}(a_i) = a_{i+1}$, for all $0 \leq i < \lambda$. The multiplication path of $c_{a_i}$ is the path in $kQ$

\[
g_v = r_{a_1}c_{a_2}r_{a_3}c_{a_4} \cdots r_{a_{\lambda-1}}c_{a_\lambda}r_{a_\lambda}
\]

If a multiplication path can be formed as a maximal overlap sequence then it is called a generative multiplication path. Note that if this is the case, $\deg(g_v) = 2\lambda$. 

43
Remark 2.4.5 If \( g_v = r_{a_1}c_{a_2}r_{a_2}c_{a_3} \cdots r_{a_{\lambda-1}}c_{a_{\lambda}}r_{a_{\lambda}} \) is a generative multiplication path then \( r_{a_1}c_{a_2}r_{a_2}c_{a_3} \cdots r_{a_{i}}c_{a_{i}}r_{a_{i}} \) is also a maximal overlap sequence, for any \( i \leq \lambda \).

Proposition 2.4.6 Let \( \Lambda \) be such that no flag0s or flag2s are present in \( T_\Lambda \) and let \( P^{2i} \) and \( Q^{2j} \) be even-degree maximal overlap sequences (of degree \( 2i \) and \( 2j \) respectively) such that the product of underlying paths \( P^{2i}Q^{2j} \) is non-zero in \( kQ \). Then the path \( P^{2i}Q^{2j} \) is also a maximal overlap sequence, of degree \( 2i + 2j \).

Proof. Consider two maximal overlap sequences \( P^{2i} \) and \( Q^{2j} \):

\[
P^{2i} = \begin{array}{c}
p_2 \quad p_3 \quad p_4 \quad \ldots \quad p_{2i-1} \quad p_{2i} \\
p_3 \quad p_4 \quad \ldots \quad p_{2i-1} \quad p_{2i}
\end{array}
\]

\[
Q^{2j} = \begin{array}{c}
q_2 \quad q_3 \quad q_4 \quad \ldots \quad q_{2j-1} \quad q_{2j} \\
q_3 \quad q_4 \quad \ldots \quad q_{2j-1} \quad q_{2j}
\end{array}
\]

Suppose that \( P^{2i}Q^{2j} \) is non-zero as a path in \( kQ \); then \( t(P^{2i}) = o(Q^{2j}) \). We need to build the path \( P^{2i}Q^{2j} \) as a maximal overlap sequence. We start with \( P^{2i} \) as above:

\[
P^{2i} = \begin{array}{c}
p_2 \quad \ldots \quad p_{2i-1} \quad p_{2i}
\end{array}
\]

By hypothesis and Theorem 2.1.19 we know we may overlap with another relation, \( p_{2i+1} \) say. Since \( t(p_{2i}) = o(q_2) \), and using the hypothesis and Theorem 2.1.19 again, we have the maximal overlap sequence:

\[
P^{2i+1} = \begin{array}{c}
p_2 \quad \ldots \quad p_{2i} \quad p_{2i+1}
\end{array}
\]

where \( p_{2(i+1)} = q_2 \) and \( p \) is the path of unoverlapped arrows. In the following diagram we can see the path \( p \) within \( Q^{2j} \).

\[
\begin{array}{c}
q_2 \\
p
\end{array}
\]

44
Thus $p$ has as an initial subpath the path of unoverlapped arrows of $Q^3$ and hence we may overlap our maximal overlap sequence above with the relation $q_4$. Using the hypothesis and Theorem 2.1.19 we get the maximal overlap sequence

$$
\begin{array}{cccccc}
\text{P2} & \ldots & \text{P2(1-1)+1} & \text{P2+1} & \text{P2+3} & \text{P2+5} \\
\text{P3} & & & & & \\
\end{array}
$$

where $p_{2(i+2)} := q_4$. We continue inductively setting $p_{2(i+k)} = q_{2k}$ for $1 \leq k \leq j$. □

**Corollary 2.4.7** Let $A$ be such that no flag0s or flag2s are present in $T_A$. If $g_v$ is a generative multiplication path then $g^l_1 \in E(\Lambda)$ is non-zero for all $l \geq 1$.

Once we have stated the following definition we will be in a position to start deciding if $E(\Lambda)$ is or is not finitely generated.

**Definition 2.4.8** If $A_w$ is an extending sequence of $E(\Lambda)$ starting at the vertex $w$ then, along with $w$ and the arrow starting at $w$, it naturally corresponds to $E_w := \text{Ext}^1_\Lambda(S_w, \Lambda)$, where $S_w$ is the simple $\Lambda$-module occurring at $w$. Then $E_w$ is a (possibly non-unital) subring of $E(\Lambda)$. We also let $E_w^{ev} := \bigoplus_{i=0}^{\infty} \text{Ext}^2_{\Lambda}(S_w, \Lambda)$ be the (possibly non-unital) subring of $E_w$ consisting of the even-degree elements.

Say that a non-unital subring $R$ of $E(\Lambda)$ has a finite generating set if there is a finite subset $S$ of $E(\Lambda)$ in which every element of $R$ may be expressed as a finite product of elements from $S$.

A maximal overlap sequence $a$ of degree $z$ is said to be in an extending sequence $A$ if $a = A^z$ for some $z \geq 2$. A generative multiplication path $g_v$ is in the lower half (respectively upper half) of an infinite extending sequence $A$ if there is some degree $z \geq 2$ and some even-degree (respectively odd-degree) maximal overlap sequence $p$ in $A$ such that $A^z = pg_v$, with the product in $E(\Lambda)$.

Using this definition we get that $E(\Lambda)$ is finitely generated as a $k$-algebra if and only if $E_w$ has a finite generating set for all $w$ such that $A_w$ is an infinite extending sequence.
Remark 2.4.9 Once and for all we take care of the basis elements of $E(\Lambda)$ of degree 0 and 1; from Chapter 1 we know these correspond respectively to the vertices and arrows of $\Lambda$. The question we resolve here is that of whether, to have a finite generating set $S$ for $\text{Ext}^2_{\Lambda}(\overline{\Lambda}, \overline{\Lambda})$, we need $S$ to include elements of $E(\Lambda)$ of degree 0 or 1. The answer is that it does not, as the next proposition shows, when used with subsequent propositions.

Proposition 2.4.10 Let $A_w$ be an infinite extending sequence and let $a$ be a maximal overlap sequence in $A_w$ of degree greater than or equal to $2M$. Let $\eta$ be an arrow in $kQ$; then $\eta$ corresponds to a basis element of $E(\Lambda)$ of degree 1 and we have the following.

1. If $\deg(a)$ is even and $a\eta \in kQ$ is non-zero in $E(\Lambda)$ then $A_w$ has a generative multiplication path in its lower half.

2. If $\deg(a)$ is odd and $a\eta \in kQ$ is non-zero in $E(\Lambda)$ then $A_w$ has a generative multiplication path in its upper half.

Proof. Let $A_w$, $a$ and $\eta$ be as above.

(1) Let $\deg(a)$ be even and $a\eta$ be non-zero in $E(\Lambda)$; we let $a_{2l}$ and $a_{2l+1}$ be the last relations of $a$ and $a\eta$ respectively. Then since $\eta$ is a path of length 1 and $\deg(a) \geq 2M$, $A_w$ must take the form

\[
\begin{array}{cccc}
\cdots & a_{2l+1} & s_3 & s_2 \\
& a_{2l} & s_2 & s_1 & s_2 & s_3 & \cdots
\end{array}
\]

with $s_{2\lambda+2} = s_2$ and $s_{2\lambda+3} = s_3$. It is immediate to see that the multiplication path starting at $s(\eta)$ is a maximal overlap sequence since clearly $s_3$ is the relation that maximally overlaps $s_2$: if $\eta$ were a longer path this need not be true. We continue building the maximal overlap sequence up to degree $2\lambda$ in the obvious way using the relations from $A_w$. Thus $A_w$ has a generative multiplication path in its lower half.

(2) Now let $\deg(a)$ be odd with $a\eta$ non-zero in $E(\Lambda)$ and let $a_{2l-1}$ and $a_{2l}$ be the last relations of $a$ and $a\eta$ respectively. Then since $\eta$ is a path of length 1 and $\deg(a) > 2M$, $A_w$ must take the form

\[
\begin{array}{cccc}
\cdots & a_{2l-1} & s_3 & s_2 \\
& a_{2l} & s_2 & s_1 & s_2 & s_3 & \cdots
\end{array}
\]

with $s_{2\lambda+2} = s_2$ and $s_{2\lambda+3} = s_3$. As before, it is immediate that the multiplication path starting at $s(\eta) = s(s_2)$ is a maximal overlap sequence and hence a generative multiplication path in the upper half of $A_w$. $\square$
Remark 2.4.11 If \( A \) satisfies one of the six conditions in Proposition 2.4.2 then the second diagram in the proof above yields the existence of an arbitrarily long odd-degree maximal overlap sequence in the position of the \( F^{2l+1} \) from Proposition 2.4.2. This contradicts that proposition and so we may conclude that condition (2) of Proposition 2.4.10 never occurs under any of the conditions from Proposition 2.4.2.

In Proposition 2.4.2 we showed that, given one of six conditions, a maximal overlap sequence could not be written as a product with a second odd-degree factor of degree greater than or equal to \( 2M + 3 \) (called \( F^{2l+1} \) in Proposition 2.4.2). Non-existence of this factor is used as a hypothesis in part of the next Proposition. The reason for this is that we want to examine the cases where we cannot use arbitrary powers of a generative multiplication path found in the upper half of an extending sequence, to get a finite generating set.

Proposition 2.4.12 Let \( A_w \) be an infinite extending sequence of \( A \).

If there is a generative multiplication path \( g_v \) in the lower half of \( A_w \) then \( E^v_w \) has a finite generating set.

Moreover, if no even-degree maximal overlap sequence \( A_{2k}^w \) in \( A_w \) may be written as a product of maximal overlap sequences \( A_{2a+1}^w F^{2l+1} Q^{2b} \), for any \( a \geq 0, l \geq M + 1, b \geq 0 \), then there is a generative multiplication path \( g_v \) in the lower half of \( A_w \) if and only if \( E^v_w \) has a finite generating set.

Proof. Let \( A_w \) be an infinite extending sequence with a generative multiplication path \( g_v \) in its lower half. Let \( G_v \) be the infinite extending sequence starting at \( v \), so that \( g_v \) is in \( G_v \). Define \( p_w \) as the maximal overlap sequence of least even-degree in \( A_w \) such that \( \deg(p_w) \geq 2M \) and \( t(p_w) = v \). We take as our generating set for \( E^v_w \):

1. The trivial path \( e_v \).

2. All even-degree maximal overlap sequences in \( A_w \) with degree less than or equal to \( \deg(p_w) \).

3. The maximal overlap sequence \( g_v \) of the hypothesis.

4. All even-degree maximal overlap sequences in \( G_v \) that have degree less than the degree of \( g_v \).
Let $a$ be an even-degree maximal overlap sequence in $A_w$. We show how to get $a$ from the above set by considering the degree of $a$.

- If $\deg(a) \leq \deg(p_w)$, then $a$ is in the chosen generating set.
- If $\deg(a) > \deg(p_w)$ then, using the remark following Definition 2.4.4, we may write $a = p_w q^{k}$, for some $k \geq 0$, and where $q$ is a maximal overlap sequence in $G_v$ of even-degree less than or equal to $\deg(q)$. We show this below:

The above product is non-zero in $E(A)$ by Proposition 2.4.6.

Conversely, suppose that we do have some finite generating set $S$ for $E_w^{nv}$ and that no maximal overlap sequence $A_{w}^{2k}$ in $A_w$ may be written as a product of maximal overlap sequences $A_{w}^{2a+1} F^{2l+1} Q^{2b}$, for any $a \geq 0$, $l \geq M + 1$, $b \geq 0$. We consider a maximal overlap sequence in $A_w$ of sufficiently high even-degree such that, in any expression of it as a product of elements of $S$, at least one element of $S$ of degree $\geq 2$ occurs with multiplicity at least 2. Without loss of generality, we may choose a maximal overlap sequence $a$ in $A_w$ with $a = h_0 d h_1 d$, where $d \in S$, $\deg(d) \geq 2$, each $h_i$ is a product of generators, $i = 0, 1$, and $\deg(h_1) \geq 2M + 1$. Now, since $\deg(h_1 d) \geq 2M + 3$ and $\deg(a)$ is even, we have by hypothesis that $\deg(h_1 d)$ is even. Thus $\deg(h_0 d)$ is even. Therefore, since $t(d) = \sigma(h_1)$, we have that the maximal overlap sequence $h_1 d$ is either a generative multiplication path, or some power (with multiplication in $E(\Lambda)$) of a generative multiplication path, in the lower half of $A_w$. □

**Theorem 2.4.13** If each infinite extending sequence of $E(\Lambda)$ contains a generative multiplication path in its lower half, then $E(\Lambda)$ is finitely generated as a $\mathbb{k}$-algebra.

**Proof.** Let $A_w$ be an infinite extending sequence with $g_v$, $p_v$ and $G_v$ as in Proposition 2.4.12. Then by Corollary 2.3.15, $T_\Lambda$ has no flag0s or flag2s. Note also that $\deg(g_v) = 2\lambda$ and $2M \leq \deg(p_w) \leq 2M + 2\lambda - 2$. From the first part of Proposition 2.4.12 we get all the even-degree maximal overlap sequences in $A_w$ with the finite generating set for $E_w^{nv}$ as given there. Now augment that generating set by including the following elements.

5. The arrow starting at $w$.
6. All odd-degree maximal overlap sequences \( s \) in \( A_w \) such that \( \deg(s) \leq \deg(p_w) + 2M + 1 \).

7. All odd-degree maximal overlap sequences \( t \) in \( G_v \) such that \( 2M + 1 \leq \deg(t) < 2M + 2\lambda + 1 \).

With this set we now describe how to get any odd-degree maximal overlap sequence \( b \) in \( A_w \). Note that the degrees are larger here than in the generating set of the last proposition for the following reason. Let \( q \) be a maximal overlap sequence in \( G_v \) of odd-degree less than \( \deg(g_v) \). Then the underlying path of \( q \) is an initial subpath of that of \( g_v \). Now, if \( b \) is of high-degree, its last relation must be a repetition relation. However, the last relation of \( q \) need not be. We must therefore choose the right-most factor of \( b \), denoted \( t \) below, to be of sufficiently high degree to end with a repetition relation. We then use Lemma 2.2.1 and Theorem 2.2.3 to give us the correct end relation for the product (this is trivial if \( \Lambda \) has only 1 repetition relation).

- If \( \deg(b) \leq \deg(p_w) + 2M + 1 \), then \( b \) is in the chosen generating set.
- If \( \deg(b) > \deg(p_w) + 2M + 1 \), then \( b = p_w g_v^k t \), for \( k \geq 0 \) and where \( t \) is some maximal overlap sequence of \( G_v \) as in 7. above, so that \( \deg(t) = \deg(b) - \deg(p_w) - k \deg(g_v) \). We illustrate \( p_w g_v^k t \) below and then prove that such a maximal overlap sequence \( b \) may indeed be expressed in this way.

\[
\begin{array}{c}
\begin{array}{ccccccc}
\square & \cdots & \square & \cdots & \square & \cdots & \square \\
p_w & & g_v^k & & t
\end{array}
\end{array}
\]

Firstly, \( p_w g_v^k t' \) is non-zero in \( E(\Lambda) \) by Proposition 2.4.6, where \( t' \) is the even-degree maximal overlap sequence in \( G_v \) of degree \( \deg(t) - 1 \). By maximality of our overlap sequences, and using the remark following Definition 2.4.4, we have that the last relation of \( t' \) is the same as that of \( b' \), where \( b' \) is the even-degree maximal overlap sequence in \( A_w \) of degree \( \deg(b) - 1 \). By Proposition 2.1.2 it is enough to show that the last relation of \( t \) is the same as the last relation of \( b \). If \( \Lambda \) has only 1 repetition relation then this is immediate, so suppose \( \Lambda \) has more than 1 repetition relation. Then, since \( G_v \) and \( A_w \) are infinite extending sequences, Theorem 2.2.3 says that \( t(t) \neq t(t') \) and \( t(b) \neq t(b') \). Moreover, since \( \deg(t) \geq 2M + 1 \), we have that the last relation of \( t \) is a repetition relation. By Lemmas 2.2.1 and 2.2.2 we have that the
last relation of \( t \) is equal to that of \( b \). Thus \( p_w g_t^k t \) is non-zero in \( E(\Lambda) \) and is equal to \( b \).

Since there are only finitely many such \( A_w \), taking the union of the above sets over each infinite \( A_w \), along with all other trivial paths, arrows and maximal overlap sequences in finite extending sequences, gives us a finite generating set for \( E(\Lambda) \).

The next two propositions examine the cases where arbitrary powers of a generative multiplication path in the upper half of an extending sequence can also be used to get a finite generating set.

**Proposition 2.4.14** Let \( \Lambda \) be such that \( \ell(r) \leq n \) for all repetition relations \( r \). Suppose one of the following occurs:

1. \( \lambda \geq 2 \), \( \Lambda \) has precisely 2 repetitions, \( N = 1 \),
2. \( \lambda \geq 2 \), \( \Lambda \) has only 1 repetition, \( 2N \equiv 1 \pmod{\lambda} \),
3. \( \lambda = 1 \), \( \Lambda \) has precisely 2 repetition relations \( r_x \) and \( r_y \).

Let \( A_w \) be an infinite extending sequence. Then \( E_w \) has a finite generating set if and only if there is a generative multiplication path \( g_v \) in the lower or upper half of \( A_w \).

**Proof.** Suppose first that \( E_w \) has a finite generating set \( S \), which we fix. We consider a maximal overlap sequence in \( A_w \) of sufficiently high even-degree such that, in any expression of it as a product of elements of \( S \), at least one element of \( S \) of degree \( \geq 2 \) occurs with multiplicity at least 3. Without loss of generality, we may choose a maximal overlap sequence \( a \) in \( A_w \) with \( a = h_0 d h_1 d h_2 d \), where \( d \in S \), \( \deg(d) \geq 2 \), each \( h_i \) is a product of generators, \( i = 0, 1, 2 \), and \( \deg(h_1) \geq 2M + 1 \).

We have that \( t(h_i) = o(d) \), for \( i = 0, 1 \) and 2. Thus \( o(d) \) is a zero-length connective path. We need to show that \( o(d) \) has a generative multiplication path. Since at least one out of \( dh_1 \), \( dh_2 \) and \( dh_1 dh_2 \) is of even degree, one of the three will be a generative multiplication path or a power of one. Thus \( A_w \) has a generative multiplication path in its lower or upper half.

Conversely, suppose \( \Lambda \) has a zero-length connective path \( e_v \) that has a generative multiplication path \( g_v \). If \( g_v \) is in the lower half of \( A_w \) then by the proof of Theorem 2.4.13 we get a finite generating set for \( E_w \). Thus suppose \( g_v \) is in the upper half of \( A_w \). Note that for condition (2), since we have only 1 repetition, \( g_v \) being in the
upper half of $A_w$ is equivalent to $g_v$ being in the lower half of $A_w$. Thus we get our
result immediately for condition (2). Define $s_w$ as the maximal overlap sequence
of least odd-degree in $A_w$, such that $\deg(s_w) \geq 2M + 1$ and $t(s_w) = v$. Let $G_v$ be
the extending sequence starting at $v$, a sequence infinite by Corollary 2.3.15 and
Proposition 2.4.6. For condition (1) we take as a finite generating set for $E_w$:

1. The trivial path $e_w$ and the arrow starting at $w$.

2. All even-degree maximal overlap sequences in $A_w$ with degree less than or
equal to $\deg(s_w) + 2M - 1$.

3. All odd-degree maximal overlap sequences in $A_w$ with degree less than or equal
to $\deg(s_w)$.

4. All even-degree maximal overlap sequences in $G_v$ with degree less than or
equal to that of $g_v$.

5. All odd-degree maximal overlap sequences $t$ in $G_v$, such that $2M + 1 \leq \deg(t) <
2M + 2\lambda + 1$.

Let $b$ be an odd-degree element of $E_w$, of degree $2l + 1$. If $l = 0$ then $b$ is an
arrow and so is itself a member of our generating set, so suppose that $l \geq 1$. Then
$b$ is a maximal overlap sequence in $A_w$.

- If $\deg(b) \leq \deg(s_w)$, then $b$ is itself in the generating set.

- If $\deg(b) > \deg(s_w)$, then using the remark following Definition 2.4.4, we may
write $b = s_w g_v^k q$, for some $k \geq 0$, and where $q$ is a maximal overlap sequence
in $G_v$ of even-degree less than or equal to $\deg(g_v)$. We show this below:

The above product is non-zero in $E(\Lambda)$ because $A$ is an infinite extending
sequence.

Let $a$ be an even-degree element of $E_w$, of degree $2l$. If $l = 0$ then $a$ is a trivial
path and so is itself a member of our generating set, so suppose that $l \geq 1$. Then $a$
is a maximal overlap sequence in $A_w$. 

51
• If \( \text{deg}(a) \leq \text{deg}(s_w) + 2M - 1 \), then \( a \) is itself in the generating set.

• If \( \text{deg}(a) > \text{deg}(s_w) + 2M - 1 \), then we write \( b = s_w g_v^k q \), for some \( k > 0 \), and where \( q \) is a maximal overlap sequence in \( G_v \) of even-degree less than or equal to \( \text{deg}(g_v) \). We show this below:

The above product is non-zero in \( E(\Lambda) \) for the following reason. Firstly, due to the maximality of the construction of \( a \), the penultimate relation \( r_f \) in \( t \), shown in the diagram above, is also the penultimate relation of \( a \). Since the length of all repetition relations is less than or equal to \( n \), we need only show that the last relation of \( a \) is equal to \( r_g \). Consider the maximal overlap sequence \( t \):

We can now deduce from the position of \( r_f \) and \( r_g \) in \( t \), and the fact that \( N = 1 \), that \( r_g \) is the last relation of \( a \).

Hence for condition (1) the given set is a finite generating set for \( E_w \).

For condition (3) we take:

1. The trivial path \( e_w \) and the arrow starting at \( w \).
2. All even-degree maximal overlap sequences in \( A_w \) with degree less than or equal to \( \text{deg}(s_w) + 2M - 1 \).
3. All odd-degree maximal overlap sequences in \( A_w \) with degree less than or equal to \( \text{deg}(s_w) \).
4. The (degree 2) maximal overlap sequence \( g_v \).
5. The maximal overlap sequence in \( G_v \) of degree \( 2M + 1 \), which we will denote by \( p_v \).

Let \( b \) be an odd-degree element of \( E_w \), of degree \( 2l + 1 \). If \( l = 0 \) then \( b \) is an arrow and so is itself a member of our generating set, so suppose that \( l \geq 1 \). Then \( b \) is a maximal overlap sequence in \( A_w \).
• If $\deg(b) \leq \deg(s_w)$, then $b$ is itself in the generating set.

• If $\deg(b) > \deg(s_w)$, then we may write $b = s_wg_v^k$, for some $k \geq 0$. We show this below:

The above product is non-zero in $E(\Lambda)$ because $A$ is an infinite extending sequence.

Let $a$ be an even-degree element of $E_w$, of degree $2l$. If $l = 0$ then $a$ is a trivial path and so is itself a member of our generating set, so suppose that $l \geq 1$. Then $a$ is a maximal overlap sequence in $A_w$.

• If $\deg(a) \leq \deg(s_w) + 2M - 1$, then $a$ is itself in the generating set.

• If $\deg(a) > \deg(s_w) + 2M - 1$, then we write $b = s_wg_v^kp_v$ for some $k \geq 0$, and where $p_v$ is a maximal overlap sequence in $G_v$ of degree equal to $2M + 1$. We show this below:

The above product is non-zero in $E(\Lambda)$ for the following reason. Firstly, due to the maximality of the construction of $a$, the penultimate relation $r_x$ in $p_v$, shown in the diagram above, is also the penultimate relation of $a$. Since the length of both repetition relations is less than or equal to $n$, we need only show that the last relation of $a$ is equal to $r_y$. Since $r_x$ and $r_y$ have to be in different repetitions, Lemma 2.3.8 gives us the last relation of $a$ equal to $r_y$.

Hence for condition (3) the given set is a finite generating set for $E_w$. □

**Proposition 2.4.15** Let $\Lambda$ be such that $\ell(r) \leq n$ for all repetition relations $r$. Suppose one of the following occurs:

1. $\lambda \geq 2$, $\Lambda$ has precisely 2 repetitions, $N = 1$,

2. $\lambda \geq 2$, $\Lambda$ has only 1 repetition, $2N \equiv 1 \pmod{\lambda}$,
3. \( \lambda = 1, \Lambda \) has precisely 2 repetition relations \( r_x \) and \( r_y \).

Then \( E(\Lambda) \) is finitely generated as a \( k \)-algebra if and only if each infinite extending sequence has a generative multiplication path in either its lower or upper half.

**Proof.** This follows immediately from Proposition 2.4.14 since \( E(\Lambda) \) is finitely generated as a \( k \)-algebra if and only if for each infinite extending sequence \( A_w \), we have a finite generating set for \( E_w \).

The last proposition in this section deals with a special case.

**Proposition 2.4.16** Let \( \Lambda \) have only one order 1 repetition relation, \( r_x \), with \( \ell(r_x) > n \), and let \( A_w \) be the single infinite extending sequence. Then \( E(\Lambda) \) is finitely generated as a \( k \)-algebra if and only if \( w = o(r_x) = t(r_x) \).

**Proof.** If \( r_x \) is the only repetition relation then from Theorem 2.3.14 we have a single unflagged row in \( T_\Lambda \), which corresponds to \( A_w \). Thus finite generation of \( E(\Lambda) \) is equivalent to \( E_w \) having a finite generating set. If \( w = o(r_x) = t(r_x) \) then we take as generating set:

1. All odd-degree maximal overlap sequences in \( A \) up to degree \( 2M + 1 \),
2. The (degree 2) maximal overlap sequence \( r_x \).

Clearly this is a finite generating set for \( E_w \).

Conversely, suppose \( E_w \) has a finite generating set. As there is only one repetition relation, and by Proposition 2.4.10, we must have a generative multiplication path in the upper or lower half of \( A_w \). Since \( r_x \) is the only repetition relation this means we must have \( o(r_x) = t(r_x) \). Now, \( r_x \) is a maximal overlap sequence (of degree 2), and by hypothesis there are no flag0s or flag2s in \( T_\Lambda \). We may therefore apply Proposition 2.4.6 to get \( o(r_x) \) the start of some infinite extending sequence \( G \). By hypothesis \( G = A_w \); hence \( w = o(r_x) \).

The following theorem is our main result and provides the classification of the finite generation of \( E(\Lambda) \) as a \( k \)-algebra.

We put Theorem 2.3.14 with Corollary 2.2.7, and Propositions 2.4.15 and 2.4.16 together to form conditions (1)-(6) in Theorem 2.4.17 below. Any conditions other than those of (1)-(6) are captured by Proposition 2.4.2. Proposition 2.4.12 and Theorem 2.4.13 then yield the stated result for these.

It is remarked here that, for any of our algebras \( \Lambda \), Theorem 2.4.13 gives sufficient conditions for \( E(\Lambda) \) to be finitely generated.
**Theorem 2.4.17** Let $\Lambda = \mathbb{k}Q/I$ be a finite-dimensional algebra, with $Q$ an oriented cycle and $I$ an admissible ideal, with the notation of the previous section. Then $E(\Lambda)$ is finite-dimensional if and only if one of the following occurs:

1. $\lambda \geq 2$, there is only 1 repetition, $N = 1$ and $\ell(r) \leq n$ for all repetition relations $r$.
2. $\lambda = 1$, there is only 1 repetition relation $r_x$ and $\ell(r_x) \leq n$.

If $E(\Lambda)$ has infinite dimension and one of the following occurs:

3. $\lambda \geq 2$, $\Lambda$ has precisely 2 repetitions, $N = 1$ and $\ell(r) \leq n$ for all repetition relations $r$,
4. $\lambda \geq 2$, $\Lambda$ has only 1 repetition, $2N \equiv 1 \pmod{\lambda}$ and $\ell(r) \leq n$ for all repetition relations $r$,
5. $\lambda = 1$, $\Lambda$ has precisely 2 repetition relations $r_x$ and $r_y$, and $\ell(r_x), \ell(r_y) \leq n$,

then $E(\Lambda)$ is finitely generated as a $\mathbb{k}$-algebra if and only if each infinite extending sequence has a generative multiplication path in either its lower or upper half.

If $E(\Lambda)$ has infinite dimension and the following occurs:

6. $\lambda = 1$, $\Lambda$ has only 1 repetition relation $r_x$ and $\ell(r_x) > n$,

then $E(\Lambda)$ is finitely generated as a $\mathbb{k}$-algebra if and only if $o(A) = o(r_x) = t(r_x)$, where $A$ is the single infinite extending sequence of $\Lambda$.

Otherwise, if $E(\Lambda)$ has infinite dimension, then $E(\Lambda)$ is finitely generated as a $\mathbb{k}$-algebra if and only if each infinite extending sequence has a generative multiplication path in its lower half.

We can now use the above theorem to yield an immediate result in some special cases; many of these algebras are considered in the literature. It should be noted that the bound on the size of the smo-tube given after Definition 2.1.12 does not grow too large next to the size of the algebra. Therefore any reasonably sized examples can easily be checked by hand.

**Corollary 2.4.18** Let $\Lambda$ have only one relation $r$ and let $\ell(r) = kn + c$, for $k \geq 0$, $0 \leq c < n$ and $\ell(r) \geq 2$.

1. If $k = 0$, then $E(\Lambda)$ is finite-dimensional.
2. If $c = 0$, then $E(\Lambda)$ is finitely generated as a $k$-algebra (with $E(\Lambda)$ finite-dimensional if $k = 1$).

3. If $k \neq 0$ and $c \neq 0$, then $E(\Lambda)$ is infinitely generated as a $k$-algebra.

**Proof.** If $k = 0$ or if $k = 1$ and $c = 0$ we are in condition (2) of the Theorem. If $k \geq 2$ and $c = 0$ we have condition (6) in Theorem 2.4.17, with $o(r) = t(r)$. If $k \neq 0$ and $c \neq 0$ we have condition (6) again, but this time $o(r) \neq t(r)$.

The algebras covered in the following corollary are those $\Lambda$ which are self-injective.

**Corollary 2.4.19** Let $J$ be the 2-sided ideal of $kQ$ generated by the arrows and let $\Lambda = kQ/J^1$, so that $\Lambda$ has $m = n$ relations, each of length $l \geq 2$. Then $E(\Lambda)$ has infinite dimension but is finitely generated as a $k$-algebra.

**Proof.** Since the tail of any relation is the head of another, any relation is the start of some infinite extending sequence. This also means each extending sequence has a generative multiplication path in its lower (and upper) half.

**Corollary 2.4.20** Let $\Lambda$ have $m$ relations, each of length $kn \geq 2$, for some fixed $k \geq 1$. Then $E(\Lambda)$ is finitely generated as a $k$-algebra. Moreover, if $m = 1$ and $k = 1$ then $E(\Lambda)$ is finite-dimensional.

**Proof.** If $m = 1$ and $k = 1$ then we are in case (2) of the theorem. If $m \neq 1$ or $k \neq 1$ then since $t(r) = o(r)$ for all relations $r$, every extending sequence is infinite so we cannot have any flags in $T_{\Lambda}$. Every relation $r$ is then the start of an infinite extending sequence that has $r$ as a (degree 2) generative multiplication path in its lower half.

**Example 2.4.21** From its smo-tube, the algebra in Example 2.1.4 can be identified as having 2 repetitions of order $\lambda = 2$. The repetition shift is $N = 1$ and the length of all repetition relations is less than or equal to $n$. We thus have condition (3), so by Theorem 2.4.17 we need to find a zero-length connective path $e_\nu$ that has a generative multiplication path $g_\nu$. From Example 2.1.8 and an inspection of the quiver we see that $e_{14}$ is a zero-length connective path, with multiplication path $g_\nu = r_{37}/r_{11}$. In this case $g_\nu$ is generative. Checking the smo-tube we find $g_\nu$ is in either the upper or lower half of each of the 4 infinite extending sequences. This gives $E(\Lambda)$ finitely generated as a $k$-algebra.
Example 2.4.22 The algebra in Example 2.1.5 can be identified as having 2 repetitions of order \( \lambda = 3 \). The repetition shift is \( N = 1 \) and the length of all repetition relations greater than \( n \). We thus fall into the "otherwise" condition of Theorem 2.4.17 and need to find two zero-length connective paths each with a generative multiplication path. From Example 2.1.9 and an inspection of the quiver we see that \( e_{12} \) is a zero-length connective path, with multiplication path \( g_v = r_6r_{21}r_{10}r_{30}r_1 \). We observe that \( g_v \) is generative since it starts an unflagged row in \( \mathcal{T}_\Lambda \). Also \( g_v \) is the only generative multiplication path. Checking the smo-tube we find \( g_v \) is in (unflagged) rows 1, 4 and 10. However, the remaining unflagged rows do not contain a generative multiplication path. This means \( E(\Lambda) \) is infinitely generated as a \( k \)-algebra.

Example 2.4.23 By slightly modifying Example 2.1.5 we can produce a markedly different Ext-algebra.

- Let \( \Lambda \) have the same quiver and relations as in Example 2.1.5, but we change \( r_{12} \) to the path \( \eta_{27} \cdots \eta_5 \), where we still have \( n < \ell(r_{12}) \leq 2n \). We still have the same smo-tube: all we have done is reduced a connective path from length 1 to length 0. This means we are still in the "otherwise" condition of Theorem 2.4.17 and so need a zero length connective path with generative multiplication path in every unflagged row of \( \mathcal{T}_\Lambda \). As can be seen from \( \mathcal{T}_\Lambda \), this example has a zero-length connective path in every unflagged row, but not a generative multiplication path. Hence \( E(\Lambda) \) is still infinitely generated.

- This time let \( \Lambda \) have the same quiver and relations as in Example 2.1.5, but we change \( r_8 \) to the path \( \eta_{18} \cdots \eta_{26} \), where we still have \( n < \ell(r_8) \leq 2n \). Again, we still have the same smo-tube: all we have done is reduced a connective path from length 1 to length 0. So we are still under the "otherwise" condition of Theorem 2.4.17. It is easy to see that this time every unflagged row of \( \mathcal{T}_\Lambda \) has a zero-length connective path with a generative multiplication path. Thus now we have \( E(\Lambda) \) finitely generated.

We close this section with a remark on generalising to monomial algebras. We also give the counter-example, provided by the authors of [18] in our June 2004 discussion, to their claim of the reverse implication of Proposition 1.2.4.
Remark 2.4.24 Let $\Gamma$ be any finite quiver; we form the path algebra $k\Gamma$. Recall that if $I$ is an admissible ideal of $k\Gamma$ generated by a finite set of paths such that $B := k\Gamma/I$ is finite-dimensional, then we say that $B$ is a monomial algebra. From Proposition 1.2.4, to determine if $E(B)$ is infinitely generated it is enough to find one infinitely generated $E(\Lambda)$ for any minimal cycle algebra $\Lambda$ overlying $B$. We can now use Theorem 2.4.17 on each overlying minimal cycle algebra $\Lambda$ to determine whether or not $E(\Lambda)$ is infinitely generated. The bound on the size of the smo-tube means that for each cycle-algebra $\Lambda$ this determination can be quickly made.

We now present an example of a monomial algebra with infinitely generated Ext-algebra, but with all overlying minimal cycle algebras having finitely generated Ext-algebra.

Example 2.4.25 [E.L.Green, D.Zacharia] Let $B$ be the $k$-algebra with quiver

![Quiver Diagram](image)

and relations $abcd, bcda, cdab, dabc, zab, daby$ and $byz$. This algebra has only one overlying minimal cycle algebra and by Theorem 2.4.17 this has finitely generated Ext-algebra. To show $E(B)$ is infinitely generated we consider basis elements in $E(B)$ with underlying path $x(abcd)^nabyz$, for $n \geq 1$. Such an element takes the form

Since multiplication relies on concatenation of paths, to non-trivially factor an element of the above form we need to split its underlying path in two at a vertex that is both the start of a relation and the end of one. So far we have many choices. However, it is clear that no matter where one chooses the split to be, the right hand path will not be a maximal overlap sequence. Thus maximal overlap sequences of the sort above cannot be non-trivially factored. Since we have infinitely many such maximal overlap sequences, $E(B)$ is infinitely generated.
2.5 Noetherian Ext-algebras

Now that we have determined precisely when $E(\Lambda)$ is finitely generated as a $k$-algebra, we determine for which cycle algebras $\Lambda$ the Ext-algebra is a Noetherian ring. In doing so we produce a class of examples for which the Ext-algebra is finitely generated but not Noetherian, and a further class that have Noetherian Ext-algebra with $\Lambda \not\cong kQ/J^n$ for any $n \geq 2$, where $J$ is the 2-sided ideal of $kQ$ generated by the arrows (algebras of the form $kQ/J^n$ are very well studied in the literature: our results do not have this restriction).

We may immediately state the main result of this section.

**Theorem 2.5.1** Let $\Lambda = kQ/I$ be a finite-dimensional algebra, with $Q$ an oriented cycle, $I$ an admissible ideal. Suppose further that the Ext-algebra $E(\Lambda)$ has infinite dimension. Then $E(\Lambda)$ is a Noetherian ring if and only if every connective path of $E(\Lambda)$ is of zero length.

Before we can prove this theorem we need the following.

**Remark 2.5.2** So far in this chapter we have talked of connective paths. In fact, just as a maximal overlap sequence is considered to be a left maximal overlap sequence if it is constructed from the left, so a left connective path and a left repetition come from an extending sequence constructed from the left. In the preceding sections, connective paths and repetitions have both been constructed from the left. This left construction of the extending sequences naturally shows the right $E(\Lambda)$-module structure of $E(\Lambda)$, which we exploit in Theorem 2.5.1. However, we also need to show how $E(\Lambda)$ behaves as a left $E(\Lambda)$-module: this is done by constructing right maximal overlap sequences. From [4] we know that left and right maximal overlap sequences have the same underlying path. In general however, the left and right repetitions need not be the same and so the left and right connective paths need not be the same. The following proposition gives us conditions under which the left and right repetitions do coincide.

**Proposition 2.5.3** Let $\Lambda$ be such that $E(\Lambda)$ has infinite dimension and suppose all left connective paths are of zero length. Then the set of left repetition relations is equal to the set of right repetition relations. In particular, all right connective paths are also of zero length.
Proof. Suppose $E(\Lambda)$ is of infinite dimension and that all left connective paths are of zero length. Let $r_{a_1}, r_{a_2}, \ldots, r_{a_\lambda}$ be the left repetition relations of $(a_1, a_2, \ldots, a_\lambda)$, one of the left repetitions of $E(\Lambda)$. Then $r_{a_1}r_{a_2}\cdots r_{a_\lambda}$ is a non-zero path in $kQ$. Since each $r_{a_i}$ is a degree 2 left maximal overlap sequence, and $E(\Lambda)$ has infinite dimension, we may use Theorems 2.1.19 and 2.3.14 and Proposition 2.4.6 to conclude that the path $h := r_{a_1}r_{a_2}\cdots r_{a_\lambda}$ is also a left maximal overlap sequence. Similarly $r_{a_1}r_{a_{i+1}}\cdots r_{a_\lambda}h^k$ is a left maximal overlap sequence for all $1 \leq i \leq \lambda$ and $k \geq 0$. Hence we can construct a left maximal overlap sequence beginning at the vertex $o(r_{a_i})$ for all $1 \leq i \leq \lambda$, of degree greater than $2M$. From [4] we have that, as a path in $kQ$, each left maximal overlap sequence of degree $l$ is also a right maximal overlap sequence of degree $l$. Thus the path $r_{a_1}r_{a_{i+1}}\cdots r_{a_\lambda}h^k$ is a right maximal overlap sequence for all $1 \leq i \leq \lambda$ and $k \geq 0$ and so $r_{a_i}$ is a right repetition relation for all $1 \leq i \leq \lambda$. We thus have that all left repetition relations are also right repetition relations. By an identical argument we get that all right repetition relations are also left repetition relations. It follows immediately that all right connective paths are of zero length. □

A dual argument yields the following corollary.

**Corollary 2.5.4** All left connective paths are of zero length if and only if all right connective paths are of zero length.

We can now prove Theorem 2.5.1.

**Proof.** (of Theorem 2.5.1). Assume first that all left connective paths of $E(\Lambda)$ are of zero length. We will show that $E(\Lambda)$ is a Noetherian right $E(\Lambda)$-module. Let $r_{b_1}, r_{b_2}, \ldots, r_{b_m}$ be the left repetition relations of $\Lambda$. Since all left connective paths are of zero length, and $E(\Lambda)$ has infinite dimension, we have by Theorems 2.1.19 and 2.3.14 that every left repetition relation is the start of a generative multiplication path. Let $g_{b_1}$ be the generative multiplication path such that $o(g_{b_1}) = o(r_{b_1})$. Set $\zeta := g_{b_1} + g_{b_2} + \cdots + g_{b_m} \in E(\Lambda)$. Then by Lemma 2.1.10, $\zeta$ is a homogeneous element of $E(\Lambda)$ in degree $2\lambda$ and has the property that $\zeta^l = g_{b_1}^l + g_{b_2}^l + \cdots + g_{b_m}^l$ for all $l \geq 1$. We thus have that 1 and $\zeta$ in $E(\Lambda)$ generate a graded subalgebra of $E(\Lambda)$ which is isomorphic to the polynomial ring in one variable, which we denote by $k[\zeta]$.

Consider the usual basis of $E(\Lambda)$ consisting of trivial paths, arrows and maximal overlap sequences constructed from the left. Since $k[\zeta]$ is a subring of $E(\Lambda)$ we consider $E(\Lambda)$ as a right $k[\zeta]$-module. Let $S' = \{A^x : A$ is an infinite extending sequence
of $E(\Lambda), 2 \leq z \leq 2M + 2\lambda - 1$ and let $S = S' \cup \{\text{trivial paths and arrows of } \Lambda\}$. We will show that $S$ is a (finite) generating set for $E(\Lambda)$ as a right $k[\zeta]$-module.

Let $A^y$ be a maximal overlap sequence of degree $y \geq 2M + 2\lambda$, in some infinite extending sequence $A$ of $E(\Lambda)$. Then $t(A^y) = t(r_{a_i})$ for some $1 \leq i \leq \mu$. Write $y - 2M = c(2\lambda) + k'$, for some $0 \leq k' < 2\lambda$, $c \geq 1$, so that $y = c(2\lambda) + k$, for some $2M \leq k \leq 2\lambda + 2M - 1$, $c \geq 1$. Then $A^y = A^kg_{\delta_i} = A^k\zeta$, with $A^k \in S$. Since $A^y$ was arbitrary we get all maximal overlap sequences of degree greater or equal to $2M + 2\lambda$ in this way. Hence $E(\Lambda)$ is finitely generated as a right $k[\zeta]$-module with generating set $S$. As $k[\zeta]$ is a Noetherian ring, we get that $E(\Lambda)$ is a Noetherian right $k[\zeta]$-module. Hence $E(\Lambda)$ is a Noetherian right $\chi(\Lambda)$-module.

Now we must show that $E(\Lambda)$ is a Noetherian left $E(\Lambda)$-module. By Proposition 2.5.3 since the left connective paths of $E(\Lambda)$ are of zero length, so are the right ones. Also the right repetition relations are the same as the left. By a similar argument to that above, it follows that $E(\Lambda)$ is finitely generated as a left $k[\zeta]$-module. That $E(\Lambda)$ is a Noetherian left $E(\Lambda)$-module then follows. Hence $E(\Lambda)$ is a Noetherian ring.

Conversely, assume now that there exists a connective path of $E(\Lambda)$ that has positive length. We can take this to be a left connective path by Corollary 2.5.4. Suppose this path starts at $t(r_{a_{i-1}})$ and ends at $\sigma(r_{a_i})$, for $r_{a_{i-1}}$ and $r_{a_i}$ repetition relations in some left repetition. The connective path is then denoted $c_{a_i}$. By taking the basis of $E(\Lambda)$ of left maximal overlap sequences, we view $E(\Lambda)$ as a right $E(\Lambda)$-module. We now construct a strictly ascending chain of right submodules of $E(\Lambda)$ that is of infinite length. First consider some special basis elements of $E(\Lambda)$, namely those left maximal overlap sequences of degree greater than $2M$ that end at $t(r_{a_{i-1}})$. Since $r_{a_{i-1}}$ is a left repetition relation, there is some extending sequence $A$ in which there are infinitely many of these maximal overlap sequences. Label these left maximal overlap sequences in $A$ that end at the vertex $t(r_{a_{i-1}})$ by $\xi_1, \xi_2, \ldots$ in increasing order of degree.

Now let $q$ be an element from our basis of $E(\Lambda)$: then $q$ corresponds to a vertex, an arrow or a left maximal overlap sequence of degree $\geq 2$. Pick $j \geq 1$; then, since $t(\xi_j) = \sigma(c_{a_i})$ and $\ell(c_{a_i}) > 0$, we get that the product $\xi_jq$ is zero in $E(\Lambda)$, for all $q \neq t(r_{a_{i-1}})$. Thus $\deg(\xi_ja) \leq \deg(\xi_j)$, for all $a \in E(\Lambda), j \geq 1$. We now construct our chain of submodules. Let $I_0 = \{0\}$ and for $j \geq 1$ let $I_j = (\xi_1, \xi_2, \ldots, \xi_j)E(\Lambda)$. Then $I_0 \subset I_1 \subset I_2 \subset \cdots$ is clearly an infinite, strictly ascending chain of right $E(\Lambda)$-submodules of $E(\Lambda)$. Hence $E(\Lambda)$ is not right Noetherian and therefore not Noetherian. QED
Recalling the definition of a minimal cycle algebra from Definition 1.2.1, we have the following corollary.

**Corollary 2.5.5** Let \( Z_Q \) be a cycle algebra overlying a minimal cycle algebra \( Z_Q \). Then \( E(Z_Q) \) is Noetherian if and only \( E(Z_Q) \) is Noetherian.

**Proof.** The result is immediate since by definition all the connective paths in \( E(Z_Q) \) are of zero length if and only if all the connective paths in \( E(Z_Q') \) are of zero length. □

Notice that Theorem 2.5.1 says nothing about the relations on \( \Lambda \) being of equal length if \( E(\Lambda) \) is Noetherian. The following example shows they need not be. Note that in both examples below, \( E(\Lambda) \) has infinite dimension.

**Example 2.5.6** Let \( Q \) be an oriented cycle with 9 vertices labelled 1, \ldots, 9. Let \( \eta_i \) be the arrow which starts at the vertex \( i \). Let \( I = \langle r_1, r_2, r_3, r_4, r_5 \rangle \), where \( r_1 = \eta_1 \eta_2 \eta_3, r_2 = \eta_2 \eta_3 \eta_4 \eta_5, r_3 = \eta_3 \eta_4 \eta_5 \eta_6, r_4 = \eta_4 \eta_5 \eta_6 \eta_7 \eta_8, r_5 = \eta_5 \eta_6 \eta_7 \eta_8 \eta_9 \). Let \( \Lambda = kQ/I \). Then the repetition relations of \( \Lambda \) are \( r_1, r_2, r_4 \) and \( r_5 \); the connective paths are the trivial paths \( e_1, e_2, e_4 \) and \( e_6 \). By Theorem 2.5.1, since \( E(\Lambda) \) has infinite dimension, we get that \( E(\Lambda) \) is Noetherian (and hence also finitely generated).

**Example 2.5.7** Let \( \Lambda \) be as in Example 2.5.6, with the exception that here \( r_4 = \eta_4 \eta_5 \eta_6 \eta_7 \eta_8 \). We have the same left repetition relations as above, but now the left connective paths are \( \eta_9, e_2, e_4 \) and \( e_6 \). Thus from Theorem 2.5.1, \( E(\Lambda) \) is not Noetherian. The positive length left connective path \( \eta_9 \) means that the \( \xi_j \)'s from the proof of Theorem 2.5.1 arise, each ending at the vertex 9. However, from Theorem 2.4.17, we get that \( E(\Lambda) \) is finitely generated.

**Remark 2.5.8** It is clear that using Theorems 2.4.17 and 2.5.1 we can extend Examples 2.5.6 and 2.5.7 in both cases to a large class of examples with the same finiteness conditions on the Ext-algebra.

Lastly we return to our discussion on monomial algebras.

**Proposition 2.5.9** Let \( B \) be a monomial algebra and let the Ext-algebra \( E(B) \) be Noetherian. Then the \( k \)-algebras \( E(Z_Q) \) are Noetherian for all minimal cycle algebras \( Z_Q \) overlying \( B \).
Proof. Let $Z_\mathcal{Q}$ be a minimal cycle algebra overlying $B$ and let $E(Z_\mathcal{Q})$ be non-Noetherian. Let $B$ have quiver $\Gamma$. We will show that $E(B)$ is non-Noetherian. By Theorem 2.5.1 we have a connective path of $E(Z_\mathcal{Q})$ of positive length, so in particular $E(Z_\mathcal{Q})$ is not right Noetherian. We thus have the infinite strictly ascending chain of right ideals of $E(Z_\mathcal{Q})$ constructed in the proof of Theorem 2.5.1. Recall that an ideal from this chain was written $I_j^{Z_\mathcal{Q}} = (\xi_1^*, \xi_2^*, \ldots, \xi_j^*)E(Z_\mathcal{Q})$. We use the $*$-notation to remain consistent with Proposition 1.2.4. As discussed in the proof of Proposition 1.2.4, each $\xi_i^*$ in $E(Z_\mathcal{Q})$ corresponds to a maximal overlap sequence $\xi_i$ in $E(B)$. We can thus form an infinite ascending chain of right ideals of $E(B)$: $I_0^B \subset I_1^B \subset I_2^B \subset \cdots$, where $I_0^B = \{0\}$ and $I_j^B = (\xi_1, \xi_2, \ldots, \xi_j)E(B)$. It remains to show that this chain is strictly ascending. Fix some $j \geq 0$ and consider the basis element $\xi_{j+1}$. To seek a contradiction suppose $I_j^B = I_{j+1}^B$. Then since $\xi_{j+1}$ is one maximal overlap sequence (not a linear combination), $\xi_{j+1} = \xi_i b$, for some $1 \leq i \leq j$ and $b$ some basis element of $E(B)$. Then the underlying path of $b$ is a terminal subpath of $\xi_{j+1}$ and so lies along the path in $\Gamma$ that is covered by $\mathcal{Q}$. Thus $b$ corresponds to a basis element $b^*$ in $E(Z_\mathcal{Q})$. This gives us $\xi_{j+1}^* = \xi_i b^*$, and so $I_j^{Z_\mathcal{Q}} = I_{j+1}^{Z_\mathcal{Q}}$. This is a contradiction and therefore we conclude that $I_j^B \neq I_{j+1}^B$. Since $j$ was arbitrary we have that our chain of right ideals of $E(B)$ is strictly ascending. Hence $E(B)$ is not Noetherian. \qed

As a counter-example to the reverse implication, Example 2.4.25 gives a monomial algebra with non-Noetherian Ext-algebra that has all its overlying minimal cycle algebras possessing Noetherian Ext-algebras.

We have now come to the end of our work on cycle algebras. The remainder of the thesis takes a different approach to looking at finiteness conditions for the Ext-algebra. We also consider algebras more general than monomial algebras.
Chapter 3

Introduction to one-point extensions and triangular matrix algebras

3.1 Triangular matrix algebras

The thesis now takes a different approach. We no longer restrict ourselves to monomial algebras; instead we broaden our outlook to all finite-dimensional associative $k$-algebras, for some field $k$. Our results now become comparison results, that is, given an algebra $A$ and some extension (like a one-point extension) $B$ of $A$, if we have some Noetherian condition on $E(A)$, what can be said about the same condition for $E(B)$? Here we introduce the concept of a triangular matrix algebra and of a one-point extension. Most of what follows in this section is taken from [3, III.2].

We start in some generality and specialise later.

**Definition 3.1.1** A ring $\Lambda$ is a triangular matrix ring if we can write $\Lambda = \left( \begin{array}{cc} T & M \\ 0 & U \end{array} \right)$, where $T$ and $U$ are rings and $T \cdot M \cdot U$ is a $T-U$-bimodule. Addition and multiplication in $\Lambda$ are given by the usual operations on matrices: $\left( \begin{array}{cc} t_1 & m_1 \\ 0 & u_1 \end{array} \right) + \left( \begin{array}{cc} t_2 & m_2 \\ 0 & u_2 \end{array} \right) = \left( \begin{array}{cc} t_1 + t_2 & m_1 + m_2 \\ 0 & u_1 + u_2 \end{array} \right)$ and $\left( \begin{array}{cc} t_1 & m_1 \\ 0 & u_1 \end{array} \right) \left( \begin{array}{cc} t_2 & m_2 \\ 0 & u_2 \end{array} \right) = \left( \begin{array}{cc} t_1 t_2 & t_1 m_2 + m_1 u_2 \\ 0 & u_1 u_2 \end{array} \right)$.

We now look at a special case of the above. Let $\Lambda$ be an Artin algebra with identity $1 = e + (1 - e)$ for some idempotent $e \neq 0,1$. We do not require $e$ or $(1 - e)$ to be primitive, but since they are both non-zero we have two new algebras, $e\Lambda e$ and $(1 - e)\Lambda(1 - e)$, and two bimodules, $e\Lambda(1 - e)$ and $(1 - e)\Lambda e$. If $e\Lambda(1 - e) = 0$, then $\Lambda$ is isomorphic to a triangular matrix ring $\left( \begin{array}{cc} (1 - e)\Lambda(1 - e) & (1 - e)\Lambda e \\ 0 & e\Lambda e \end{array} \right)$.
and we say Λ is a triangular matrix algebra. If Λ is a path algebra or a quotient of one then (conversely to [3]) we will write paths from left to right, as we have done throughout the thesis.

The category mod-Λ is described via an equivalence with the categories CΛ and ĈΛ, given in [3] and which we describe now.

**Definition 3.1.2** [3] Let Λ be a triangular matrix k-algebra as in Definition 3.1.1. Let CΛ be the category whose objects are the triples (A, B, f) with A in mod-T, B in mod-U and f : A ⊗T M → B a morphism of right U-modules. The morphisms between two objects (A, B, f) and (A', B', f') are pairs of morphisms (α, β) where α : A → A' is a T-morphism and β : B → B' is a U-morphism such that the diagram

\[
\begin{array}{ccc}
A ⊗_T M & \overset{α \otimes \text{id}}{\longrightarrow} & A' ⊗_T M \\
\downarrow f & & \downarrow f' \\
B & \overset{\beta}{\longrightarrow} & B'
\end{array}
\]

commutes. If (α1, β1) and (α2, β2) are morphisms in CΛ then their sum is defined as summing componentwise: (α1, β1) + (α2, β2) = (α1 + α2, β1 + β2).

We also define a second category ĈΛ. Note that, in the definition below, the k-vector space HomU(M, B) can be considered as a right T-module by setting (δt)(m) := δ(tm), for δ ∈ HomU(M, B), t in T and m in M. We thus have the adjoint functors

\[ - ⊗_T M : \text{mod}-T \longrightarrow \text{mod}-U \]

\[ \text{Hom}_U(M, -) : \text{mod}-U \longrightarrow \text{mod}-T \]

giving the adjoint isomorphism \(ψ : \text{Hom}_U(A ⊗_T M, B) \rightarrow \text{Hom}_T(A, \text{Hom}_U(M, B))\), where A is a right T-module and B is a right U-module.

**Definition 3.1.3** [3] Let Λ be a triangular matrix k-algebra as in Definition 3.1.1. Let ĈΛ be the category whose objects are triples (A, B, g), where A is in mod-T, B is in mod-U and g : A → HomU(M, B) is a morphism of right T-modules. The morphisms between two objects (A, B, g) and (A', B', g') are pairs of morphisms (α, β) where α : A → A' is a T-morphisms and β : B → B' is a U-morphism such that the diagram

\[
\begin{array}{ccc}
A & \overset{α}{\longrightarrow} & A' \\
\downarrow g & & \downarrow g' \\
\text{Hom}_U(M, B) & \overset{β^*}{\longrightarrow} & \text{Hom}_U(M, B')
\end{array}
\]

commutes, where \(β^*\) is induced from β. As in CΛ, summing of morphisms in ĈΛ is defined as summing componentwise.
The composition of morphisms in \( C \) and in \( \tilde{C} \) is given by \((\alpha_1, \beta_1)(\alpha_2, \beta_2) = (\alpha_1\alpha_2, \beta_1\beta_2)\).

**Definition 3.1.4** A preadditive category (sometimes called an Ab-category) is a category such that every Hom-set \( \text{Hom}(A, B) \) is an Abelian group and composition distributes over the operation of addition. Thus if we have a diagram

\[
A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D
\]

then \( f(g + g')h = fgh + fg'h \) in \( \text{Hom}(A, D) \). This is equivalent to the composition map \( \text{Hom}(X, Y) \times \text{Hom}(Y, Z) \to \text{Hom}(X, Z) \) being bilinear.

A \( k \)-category is a preadditive category where the bilinear map associated with morphism composition is \( k \)-bilinear.

**Lemma 3.1.5** [3] The categories \( C \) and \( \tilde{C} \) are \( k \)-additive categories.

**Proof.** It is easily checked that \( C \) and \( \tilde{C} \) are categories. Now let the following be a diagram in either \( C \) or \( \tilde{C} \).

\[
(A, X, f) \xrightarrow{(\alpha_1, \beta_1)} (B, Y, g) \xrightarrow{(\alpha_2, \beta_2)} (C, Z, h) \xrightarrow{(\alpha_3, \beta_3)} (D, W, l)
\]

Note that for a scalar \( k \in k \) and a morphism \((\alpha, \beta)\) in \( C \) or \( \tilde{C} \), we have \( k(\alpha, \beta) = (k\alpha, k\beta) \). This, along with the definition given for addition of morphisms, means the Hom-sets in \( C \) and the Hom-sets in \( \tilde{C} \) inherit a \( k \)-vector space property from Hom-sets in mod-\( T \) and mod-\( U \). For scalars \( k_2 \) and \( k_3 \), we now just need the identity:

\[
(\alpha_1, \beta_1)[k_2(\alpha_2, \beta_2) + k_3(\alpha_3, \beta_3)](\alpha_4, \beta_4)
\]

\[
= (\alpha_1, \beta_1)[(k_2\alpha_2 + k_3\alpha_3, k_2\beta_2 + k_3\beta_3)](\alpha_4, \beta_4)
\]

\[
= (\alpha_1, \beta_1)(k_2\alpha_2 + k_3\alpha_3, k_2\beta_2 + k_3\beta_3)(\alpha_4, \beta_4)
\]

\[
= (\alpha_1(k_2\alpha_2 + k_3\alpha_3)\alpha_4, \beta_1(k_2\beta_2 + k_3\beta_3)\beta_4)
\]

\[
= (k_2\alpha_1\alpha_2\alpha_4 + k_3\alpha_1\alpha_3\alpha_4, k_2\beta_1\beta_2\beta_4 + k_3\beta_1\beta_3\beta_4)
\]

\[
= (k_2(\alpha_1\alpha_2\alpha_4, k_1\alpha_2\beta_2\beta_4) + (k_3\alpha_1\alpha_3\alpha_4, k_3\beta_1\beta_3\beta_4)
\]

\[
= k_2((\alpha_1, \beta_1)(\alpha_2, \beta_2)(\alpha_3, \beta_3)(\alpha_4, \beta_4)
\]

Thus \( C \) and \( \tilde{C} \) are \( k \)-categories. \( \square \)
We will now see that there is an equivalence between the categories \( \text{mod-}\Lambda \) and \( \mathcal{C}_\Lambda \), and an isomorphism of categories between \( \mathcal{C}_\Lambda \) and \( \tilde{\mathcal{C}}_\Lambda \). The functors defining these equivalences are given in the definition below. Let \( \Lambda \) be as in Definition 3.1.1.

**Definition 3.1.6** [3]

1. Let \( F : \mathcal{C}_\Lambda \rightarrow \text{mod-}\Lambda \) be the functor defined as follows. For \((A, B, f)\) in \( \mathcal{C}_\Lambda \) we define \( F(A, B, f) = A \oplus B \) as an Abelian group under addition, and with the \( \Lambda \)-module structure given by \((a, b) \mapsto \begin{pmatrix} t & m \\ 0 & u \end{pmatrix} = (at, f(a \otimes m) + bu)\), for \( a \in A, b \in B, t \in T, u \in U \) and \( m \in M \). If \((\alpha, \beta) : (A, B, f) \rightarrow (A', B', f')\) is a morphism in \( \mathcal{C}_\Lambda \) then \( F(\alpha, \beta) = \alpha \oplus \beta : A \oplus B \rightarrow A' \oplus B' \).

2. Let \( H : \mathcal{C}_\Lambda \rightarrow \tilde{\mathcal{C}}_\Lambda \) be the functor defined by \( H(A, B, f) = (A, B, \psi(f)) \) on objects and \( H(\alpha, \beta) = (\alpha, \beta) \) on morphisms, where \( \psi \) is the adjoint isomorphism described earlier.

We now get the following result, referring the reader to [3] for the proof.

**Proposition 3.1.7** [3]

1. The functor \( F : \mathcal{C}_\Lambda \rightarrow \text{mod-}\Lambda \) defined above is an equivalence of categories.

2. The functor \( H : \mathcal{C}_\Lambda \rightarrow \tilde{\mathcal{C}}_\Lambda \) defined above is an isomorphism of categories.

Armed with these categorical equivalences we will be well positioned to present our main results about triangular matrix algebras in Chapter 4. In the next section however, we will specialise to discuss one-point extensions.

### 3.2 One-point extensions

We now give the definition of a one-point extension, which is a specialisation of a triangular matrix ring.

**Definition 3.2.1** Let \( B = \begin{pmatrix} T & M \\ 0 & A \end{pmatrix} \) be a triangular matrix ring (so \( A \) and \( T \) are rings, \( M \) a \( T\)-\( A \)-bimodule). If \( T \) is a division ring then \( B \) is a one-point extension of \( A \) by the bimodule \( T M_A \). In this case we write \( A[M] := B \).
In the context of finite-dimensional algebras over a field $k$ we have $T = k$. Since $M$ is a $k$-vector space we have that $kM$ is a left $k$-module, and so in this way $kM_A$ is a $k$-$A$-bimodule. The quiver of $B = A[M]$ has a source vertex $i$ (no arrows going in to $i$) corresponding to the $k$ in the upper left corner of the matrix of $B$. We say that $B$ is a one-point extension of the algebra $A$, where the quiver of $A$ is that of $B$ but with the source vertex $i$ (and therefore any arrows leaving $i$) removed. The relations for $A$ are those of $A[M]$, less any that start at $i$. More concretely, let $e_i$ be the primitive idempotent corresponding to the vertex $i$. Then, since $i$ is a source, we have $e_iA[M]e_i = k$ and $(1 - e_i)A[M]e_i = 0$. As seen in Section 3.1, we can now write $A[M] = \begin{pmatrix} k & e_iA[M](1 - e_i) \\ 0 & A \end{pmatrix}$, so that $A[M]$ is a one-point extension of $A$.

It happens that there is a natural way to view $A$-modules as $A[M]$-modules. We formalise this with the following functor.

**Definition 3.2.2** Define a functor $\mathcal{F} : \text{mod-}A \to \text{mod-}A[M]$ by $\mathcal{F}(X) = (0, X)$, for $X \in \text{mod-}A$, and $\mathcal{F}(f) = \begin{pmatrix} 0 & 0 \\ 0 & f \end{pmatrix}$, for $f : X \to Y$ a morphism in $\text{mod-}A$.

The $A[M]$-action on $(0, X)$ is given by $(0, X)A[M] = (0, X)\begin{pmatrix} k & M \\ 0 & A \end{pmatrix} = (0, XA)$ and so is the same as the $A$-action on $X$. Also for all $f \in \text{Hom}_A(X, Y)$ we have $(0, X)\mathcal{F}(f) = (0, X)\begin{pmatrix} 0 & 0 \\ 0 & f \end{pmatrix} = (0, (X)f)$ and so $\mathcal{F}(f) \in \text{Hom}_{A[M]}(\mathcal{F}(X), \mathcal{F}(Y))$.

**Lemma 3.2.3** $\mathcal{F}$ is a full, faithful and exact functor.

**Proof.** To show $\mathcal{F}$ is a functor we observe first that $\mathcal{F}(X)$ exists for all $X \in \text{mod-}A$ and that $\mathcal{F}(f)$ exists in $\text{Hom}_{A[M]}(\mathcal{F}(X), \mathcal{F}(Y))$ for all $f \in \text{Hom}_A(X, Y)$ as above. Now, given $\text{id} : X \to X$ we have $\mathcal{F}(\text{id}) : \mathcal{F}(X) \to \mathcal{F}(X)$. Let $(0, x)$ be an arbitrary element of $\mathcal{F}(X)$. Then $(0, x)\mathcal{F}(\text{id}) = (0, x)\begin{pmatrix} 0 & 0 \\ 0 & \text{id} \end{pmatrix} = (0, (x)\text{id}) = (0, x)$. Hence $\mathcal{F}$ takes identity morphisms to identity morphisms. Now let $X \xrightarrow{f} Y \xrightarrow{g} Z$ be a diagram in $\text{mod-}A$. This gives rise to a diagram $\mathcal{F}(X) \xrightarrow{\mathcal{F}(f)} \mathcal{F}(Y) \xrightarrow{\mathcal{F}(g)} \mathcal{F}(Z)$ in $\text{mod-}A[M]$. Let $(0, x)$ be an arbitrary element of $\mathcal{F}(X)$. Then $(0, x)\mathcal{F}(f)\mathcal{F}(g) = (0, x)\begin{pmatrix} 0 & 0 \\ 0 & f \end{pmatrix}\begin{pmatrix} 0 & 0 \\ 0 & g \end{pmatrix} = (0, (x)f)\begin{pmatrix} 0 & 0 \\ 0 & g \end{pmatrix} = (0, ((x)f)g) = (0, (x)(fg)) = (0, x)\mathcal{F}(fg)$. Thus $\mathcal{F}$ is a functor.

Clearly $\mathcal{F}$ is faithful and full. To show that $\mathcal{F}$ is exact, consider a short exact sequence in $\text{mod-}A$: $0 \to X \xrightarrow{f} Y \xrightarrow{g} Z \to 0$. This gives rise to a diagram
in $\text{mod-}A[M]$: $0 \xrightarrow{0} (0, X) \xrightarrow{\mathcal{F}(f)} (0, Y) \xrightarrow{\mathcal{F}(g)} (0, Z) \xrightarrow{0}$; we show it is a short exact sequence. Now

$$\ker \mathcal{F}(f) = \{(0, x) \in (0, X) : (0, x) \mathcal{F}(f) = 0\}$$

$$= \{(0, x) \in (0, X) : (0, (x)f) = 0\}$$

$$= \{(0, x) \in (0, X) : (x)f = 0\}$$

$$= \mathcal{F}\{x \in X : (x)f = 0\}$$

$$= \mathcal{F}(\ker f) = \mathcal{F}(0) = 0$$

and

$$\text{im } \mathcal{F}(g) = \{(0, z) \in (0, Z) : \exists (0, y) \in (0, Y) \text{ with } (0, y) \mathcal{F}(g) = (0, z)\}$$

$$= \{(0, z) \in (0, Z) : \exists y \in Y \text{ with } (0, (y)g) = (0, z)\}$$

$$= \{(0, z) \in (0, Z) : \exists y \in Y \text{ with } (y)g = z\}$$

$$= \mathcal{F}\{z \in Z : \exists y \in Y \text{ with } (y)g = z\}$$

$$= \mathcal{F}(\text{im } g) = \mathcal{F}(0, Z),$$

so we have exactness at $(0, X)$ and $(0, Z)$. To get exactness at $(0, Y)$ we just have to observe that $\ker(\mathcal{F}(g)) = \mathcal{F}(\ker(g)) = \mathcal{F}(\text{im}(f)) = \text{im}(\mathcal{F}(f))$. Hence $\mathcal{F}$ is a fully faithful, exact functor. □

Let us now look at how we construct a one-point extension of a $k$-algebra $A = kQ/I$ and an $A$-module $M_A$. We want to describe $A[M]$ by quiver and relations. Let $Q_0$ and $Q_1$ be the vertices and arrows of $Q$ respectively, and let the relations of $A$ be $r_1, \ldots, r_t$. Then $M$ has a minimal projective presentation over $A$:

$$\bigoplus_{j=1}^n w_j A \xrightarrow{\phi} \bigoplus_{i=1}^n v_i A \xrightarrow{} M \xrightarrow{} 0$$

where the $v_i$'s and $w_j$'s are trivial paths in $A$. We can describe $\phi$ as a matrix. Consider the action of $\phi$ on some $w_j$. We have $\phi(w_j) = \sum_{i=1}^n v_i f_{ij}$, for some $f_{ij} \in v_i A$. Note the $f_{ij}$'s might themselves be linear combinations. Since $\phi$ is defined by its action on the generators of the domain, it is defined by the $f_{ij}$'s. Now, since $\phi$ is a homomorphism and $w_j$ is an idempotent, we have the non-zero equality $\sum_{i=1}^n v_i f_{ij} = \phi(w_j) = \phi(\phi(w_j)) = \phi(w_j)w_j = \sum_{i=1}^n v_i f_{ij} w_j$, for each $j$. This means that $v_i f_{ij} = v_i f_{ij} w_j$, for each $i$, and so $f_{ij} \in v_i A w_j$, for all $i$ and $j$. 69
To get the quiver for $A[M]$ from that of $A$ we add a single new source vertex, $v^*$, and $n$ new arrows $a_1^*, \ldots, a_n^*$, with each $a_i^*$ starting at $v^*$ and ending at the vertex $v_i$ in $Q$; thus there is one new arrow for each generator of the projective cover of $M$.

The extra relations come from the second projective in the presentation of $M$.

More precisely, the one-point extension $A[M]$ has quiver with vertices $Q_0 \cup \{v^*\}$ and arrows $Q_1 \cup \{a_i^*\}$, where $a_i^*$ is an arrow from $v^*$ to $v_i$, for $i = 1, \ldots, n$. The relations on $A[M]$ are $\{r_1, \ldots, r_l\} \cup \{s_j^*\}$, where $s_j^* = \sum_{i=1}^n a_i^* f_{ij}$, for $j = 1, \ldots, m$.

### 3.3 Useful results

We first give two results from ring theory. The proof of the first can be found in [1]; we give the proof of the second for completeness.

**Proposition 3.3.1** [1, 10.12] Let $R$ be a ring and let $0 \to K \to M \to N \to 0$ be an exact sequence of $R$-modules. Then $M$ is Noetherian if and only if both $K$ and $N$ are Noetherian.

**Proposition 3.3.2** [1, 10ex7] Let $\phi : Q \to R$ be a ring homomorphism and let $M$ be a right $R$-module. Then $M$ is a right $Q$-module via $\phi$, and moreover, if $M_Q$ is Noetherian then so is $M_R$.

**Proof.** Firstly, the action of $Q$ on $M$ is given by $m \cdot q := m \cdot \phi(q)$, for $m \in M$, $q \in Q$. It is easy to check that since $\phi$ is a ring homomorphism we get that $M$ is a $Q$-module.

Secondly, let $N_0 \subset N_1 \subset N_2 \subset \cdots$ be an ascending chain of $R$-submodules of $M_R$. Via $\phi$ we get that every $R$-module is also a $Q$-module. Hence $N_0 \subset N_1 \subset N_2 \subset \cdots$ is an ascending chain of $Q$-submodules of $M_Q$. Since $M_Q$ is Noetherian we get that $N_i = N_{i+p}$, for some $i \geq 0$ and for all $p \geq 0$. Hence $M_R$ is Noetherian. \(\square\)
Chapter 4

Ext-algebras of one-point extensions and of triangular matrix algebras

4.1 One-point extensions

In this chapter we present some results found on comparing the Ext-algebra of a finite-dimensional algebra with that of its one-point extension, and then a slight generalisation where we look at how the Ext-algebra of a triangular matrix algebra compares to those of its two constituent algebras. The quality we study is that of the Ext-algebra being left or right Noetherian as a \( k \)-algebra. We begin with some preliminary constructions.

Let \( A \) be a finite-dimensional \( k \)-algebra and let \( M \) be a finitely generated right \( A \)-module. We can thus form the one-point extension of \( A \) with respect to \( M \), denoted by \( B = A[M] := \begin{pmatrix} k & M \\ 0 & A \end{pmatrix} \). It is clear that due to the operations of addition and multiplication for \( B \), we have a subalgebra \( \begin{pmatrix} 0 & 0 \\ 0 & A \end{pmatrix} \) which is isomorphic to \( A \).

Let \( E(A) \) be the Ext-algebra of \( A \) and \( E(B) \) be the Ext-algebra of \( B \). Let \( r \) and \( r' \) be the Jacobson radicals of \( A \) and \( B \) respectively. Then using our functor \( \mathcal{F} \) from Definition 3.2.2 we have \( B/r' = \mathcal{F}(A/r) \oplus S_w \), where we now write \( w := v^* \) for the
extra vertex. Recall that \( \Omega(S_w) = \mathcal{F}(M) \). We then have as vector-spaces:

\[
E(B) = \text{Ext}^*_B(B/\ell', B/\ell')
\]

\[
\cong \text{Ext}^*_B(\mathcal{F}(A/\ell), \mathcal{F}(A/\ell)) \oplus \text{Ext}^*_B(S_w, S_w) \oplus \text{Ext}^*_B(\mathcal{F}(A/\ell), S_w) \oplus \text{Ext}^*_B(S_w, \mathcal{F}(A/\ell))
\]

\[
\cong \text{Ext}^*_A(A/\ell, A/\ell) \oplus \text{Hom}_B(S_w, S_w) \oplus 0 \oplus \bigoplus_{i=1}^{\infty} \text{Ext}^*_B(S_w, \mathcal{F}(A/\ell))
\]

\[
\cong E(A) \oplus \text{Hom}_B(S_w, S_w) \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^*_B(\mathcal{F}(M), \mathcal{F}(A/\ell))
\]

\[
\cong E(A) \oplus \text{Hom}_B(S_w, S_w) \oplus \text{Ext}^*_A(M, A/\ell).
\]

The first thing we notice is that \( \text{Ext}^*_A(M, A/\ell) \) is naturally a right \( E(A) \)-module. In the following proposition we will show that if \( E(A) \) is a right Noetherian ring then \( \text{Ext}^*_A(M, A/\ell) \) is finitely generated as a right \( E(A) \)-module, by proceeding by induction on the radical length of \( M \). Note first that \( M \) is a finitely generated module over the (right) Noetherian ring \( A \). This means \( M \) is a Noetherian \( A \)-module. We will need the following well-known proposition, the proof of which we include for completeness.

**Proposition 4.1.1** Let \( A \) be a finite-dimensional algebra with \( E(A) \) a right Noetherian ring, and let \( N \) be a finitely generated right \( A \)-module. Then \( \text{Ext}^*_A(N, A/\ell) \) is a finitely generated right \( E(A) \)-module.

**Proof.** As noted above, \( \text{Ext}^*_A(N, A/\ell) \) is naturally a right \( E(A) \)-module. We show that it is finitely generated as a right \( E(A) \)-module by proceeding by induction on the radical length of \( M \).

If \( N_\ell = 0 \) then \( N \) is the direct sum of finitely many simple right \( A \)-modules. Therefore \( \text{Ext}^*_A(N, A/\ell) \in \text{Add}^f \left( E(A)_{E(A)} \right) \), the category of finite sums of summands of the right regular \( E(A) \)-module. This means \( \text{Ext}^*_A(N, A/\ell) \) is finitely generated as a right \( E(A) \)-module.

For the inductive hypothesis, suppose \( \exists n \geq 2 \) such that if \( N \) is a finitely generated right \( A \)-module with \( N_\ell^{n-1} = 0 \), then \( \text{Ext}^*_A(N, A/\ell) \) is a finitely generated right \( E(A) \)-module.

For the inductive step suppose \( N \) is some finitely generated \( A \)-module with \( N_\ell^n = 0 \). We form the short exact sequence

\[
0 \longrightarrow N_\ell \longrightarrow N \longrightarrow N/N_\ell \longrightarrow 0
\]

72
Applying the contravariant functor $\text{Hom}_A(-, A/\mathbb{E})$ we get a long exact sequence in cohomology:

\[
\begin{array}{c}
0 \longrightarrow \text{Hom}_A(N/N_\mathbb{E}, A/\mathbb{E}) \overset{f_0}{\longrightarrow} \text{Hom}(N, A/\mathbb{E}) \overset{g_0}{\longrightarrow} \text{Hom}(N_\mathbb{E}, A/\mathbb{E}) \\
\downarrow \text{Ext}^1_A(N/N_\mathbb{E}, A/\mathbb{E}) \overset{f_1}{\longrightarrow} \text{Ext}^1(N, A/\mathbb{E}) \overset{g_1}{\longrightarrow} \text{Ext}^1(N_\mathbb{E}, A/\mathbb{E}) \\
\downarrow \text{Ext}^2_A(N/N_\mathbb{E}, A/\mathbb{E}) \overset{f_2}{\longrightarrow} \text{Ext}^2(N, A/\mathbb{E}) \overset{g_2}{\longrightarrow} \text{Ext}^2(N_\mathbb{E}, A/\mathbb{E}) \longrightarrow \cdots
\end{array}
\]

which yields the exact sequence

\[
\text{Ext}^*_A(N/N_\mathbb{E}, A/\mathbb{E}) \overset{f_*}{\longrightarrow} \text{Ext}^*_A(N, A/\mathbb{E}) \overset{g_*}{\longrightarrow} \text{Ext}^*_A(N_\mathbb{E}, A/\mathbb{E})
\]

with $f_*$ and $g_*$ acting componentwise. For ease of notation let $R = E(A)$, $K = \text{Ext}^*_A(N/N_\mathbb{E}, A/\mathbb{E})$, $L = \text{Ext}^*_A(N, A/\mathbb{E})$ and $Q = \text{Ext}^*_A(N_\mathbb{E}, A/\mathbb{E})$. This gives us the exact sequence of $R$-modules

\[
K \overset{f_*}{\longrightarrow} L \overset{g_*}{\longrightarrow} Q
\]

from which we get the diagram

\[
\begin{array}{ccc}
K & \overset{f_*}{\longrightarrow} & L \\
\downarrow f_* & & \downarrow g_* \\
\text{im} f_* & & \text{im} g_* \\
\end{array}
\]

Since $\text{im} f_* = K/\ker f_*$ by the first isomorphism theorem, and $\ker g_* = \text{im} f_*$ by exactness, we have the short exact sequence

\[
0 \longrightarrow K/\ker f_* \longrightarrow L \longrightarrow \text{im} g_* \longrightarrow 0
\]

Using the induction hypothesis, $K$ is a finitely generated $R$-module and so we have that $K/\ker f_*$ is a finitely generated $R$-module and hence is Noetherian. Also by the inductive hypothesis, $Q$ is a finitely generated $R$-module and since $R$ is Noetherian this means the submodule $\text{im} g_*$ is finitely generated and hence Noetherian. We now apply Proposition 3.3.1 to get $L$ Noetherian as a right $R$-module and hence finitely generated. Thus $\text{Ext}^*_A(N, A/\mathbb{E})$ is a finitely generated $E(A)$-module.

Hence by induction if $N$ is a finitely generated right $A$-module then $\text{Ext}^*_A(N, A/\mathbb{E})$ is a finitely generated right $E(A)$-module. \qed
We now come to the theorem of this section.

**Theorem 4.1.2** Let $A$ be a finite-dimensional $k$-algebra and let $M$ be a finitely generated right $A$-module. Let $B = A[M]$ be the one-point extension of $A$ by $M$.

If $E(A)$ is a right Noetherian ring then $E(B)$ is a right Noetherian ring.

**Proof.** To show that $E(B)$ is a right Noetherian ring we start by finding a right Noetherian unital subring. The subring $E(A)$ has unit $1_{E(A)} = e_1 + \cdots + e_n$, where $e_i$ is the identity map in $\text{Hom}_A(S_i, S_i)$, each simple $A$-module $S_i$, $1 \leq i \leq n$. However $E(B)$ has unit $1_{E(B)} = e_1 + \cdots + e_n + e_w$, where $e_w$ is the identity on the extra simple module $S_w$. We thus consider the subring $R = E(A) \oplus \text{Hom}(S_w, S_w)$, with multiplication defined componentwise. This is a unital subring of $E(B)$. We need to show $R$ is right Noetherian as a ring, that is, it is a Noetherian right module over itself. First consider $E(A)$ as a right $R$-module. The action of $R$ on $E(A)$ is identical to that of $E(A)$ on $E(A)$, since there are no non-zero products between $E(A)$ and $\text{Hom}(S_w, S_w)$. Hence if $E(A)_R$ is Noetherian then $E(A)_R$ is Noetherian. Similarly since $\text{Hom}_B(S_w, S_w)$ is a right Noetherian $\text{Hom}_B(S_w, S_w)$-module we have that it is a right Noetherian $R$-module. Thus we have a short exact sequence of right $R$-modules

$$0 \longrightarrow \text{Hom}_B(S_w, S_w) \longrightarrow R \longrightarrow E(A) \longrightarrow 0$$

with the first and third terms Noetherian $R$-modules. By Proposition 3.3.1 $R$ is a Noetherian right $R$-module. Hence $R$ is a right Noetherian unital subring of $E(B)$. Now, since $\text{Ext}^+_A(M, A/\ell)$ is a finitely generated right $E(A)$-module, it is certainly finitely generated as a right $R$-module. We thus have that $E(B) = R \oplus \text{Ext}^+_A(M, A/\ell)$ is finitely generated as a right $R$-module, and so $E(B)_R$ is Noetherian.

Using Proposition 3.3.2 with the injective unital ring homomorphism $R \xrightarrow{\phi} E(B)$ we get that $E(B)$ is a right Noetherian $E(B)$-module. Therefore $E(B)$ is a right Noetherian ring. □

The above theorem is quite general, so although we illustrate it with the following example, the reader should note that we could have chosen any finitely generated module $M$.  

74
Example 4.1.3 Let $A$ be the algebra given in Example 2.5.6. This has quiver $Q$ given by

![Quiver Diagram]

and relations $r_1 = \eta_1 \eta_2 \eta_3$, $r_2 = \eta_2 \eta_3 \eta_4 \eta_5$, $r_3 = \eta_3 \eta_4 \eta_5 \eta_6$, $r_4 = \eta_4 \eta_5 \eta_6 \eta_7 \eta_8 \eta_9$, $r_5 = \eta_5 \eta_7 \eta_8 \eta_9 \eta_1$. Thus $A = kQ/I$, where $I = \langle r_1, r_2, r_3, r_4, r_5 \rangle$. By Theorem 2.5.1 we have that $E(A)$ is a right Noetherian ring. We can decompose $A$ as a right $A$-module into the indecomposable projective $A$-modules:

\[
\begin{array}{cccccccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
2 & & & & & & & & & & & \\
3 & & & & & & & & & & & \\
4 & & & & & & & & & & & \\
5 & & & & & & & & & & & \\
6 & & & & & & & & & & & \\
7 & & & & & & & & & & & \\
8 & & & & & & & & & & & \\
9 & & & & & & & & & & & \\
\end{array}
\]

As with all monomial cycle algebras, the indecomposable modules are all uniserial. Label the trivial paths $e_i$, for $1 \leq i \leq 9$, in the usual way, so that the right $A$-modules $e_i A$ are the indecomposable projective modules. Let

\[
M = e_2 A \oplus (e_4 A/\eta_4 A) \oplus (e_6 A/\eta_6 \eta_7 \eta_8 \eta_9 A) \oplus (e_7 A/\eta_7 \eta_8 A).
\]

Then $M$ is a right $A$-module with composition series:

\[
\begin{array}{ccccccc}
2 & 4 & 6 & 7 & & & \\
3 & & & & & & \\
4 & & & & & & \\
5 & & & & & & \\
\end{array}
\]

and with a projective $A$-presentation:

\[
e_5 A \oplus e_1 A \oplus e_9 A \xrightarrow{\phi} e_2 A \oplus e_4 A \oplus e_6 A \oplus e_7 A \longrightarrow M \longrightarrow 0
\]
This gives us the following matrix for \( \phi \):

\[
\phi = \begin{pmatrix}
0 & 0 & 0 \\
\eta_4 & 0 & 0 \\
0 & \eta_6 \eta_7 \eta_8 \eta_9 & 0 \\
0 & 0 & \eta_7 \eta_8 \\
\end{pmatrix}
\]

Thus \( A[M] \) has quiver as follows. We label the \( \alpha_i \)'s in accordance with the end vertex of each, so that \( \alpha_i \) ends at \( i + 1 \).

and the relations are those of \( A \) together with \( \alpha_3 \eta_4 \), \( \alpha_5 \eta_6 \eta_7 \eta_8 \eta_9 \) and \( \alpha_6 \eta_7 \eta_8 \). The new indecomposable projective module, \( e_{u^*} A[M] \), has composition series shown below.

We can now use Theorem 4.1.2 to conclude that \( E(A[M]) \) is a right Noetherian ring.

To produce a non-monomial algebra we can repeat the one-point extension construction. Let \( B := A[M] \) and consider the right \( B \)-module

\[
N = (e_{u^*} B \oplus (e_2 B / \eta_2 \eta_3 \eta_4 B)) / \langle \langle \alpha_3, -\eta_7 \eta_3 + \eta_2 \eta_3 \eta_4 B \rangle \rangle.
\]

Then \( N \) has composition series shown below.
We will now show that $N$ is indecomposable; this will be done by showing that the quotient module of $N$, which we call $N'$ (and give its composition series below), is indecomposable.

\[
N' = \begin{array}{ccc}
 & 2 \\
1 & v^* & 3 \\
 & 4 &
\end{array}
\]

The non-zero part of the representation for $N'$ comes from the following part of the quiver of $A[M]$:

\[
\begin{array}{ccc}
2 & 3 & 4 \\
\alpha_2 & \alpha_4 \\
v^* &
\end{array}
\]

and is given as

\[
\begin{array}{ccc}
0 & k & k \\
k & a & b \\
k & c & k \\
& k & k
\end{array}
\]

for some non-zero maps $a$, $b$ and $c$. Computing the endomorphism ring below, we see that all connecting maps must equal the first we choose:

\[
\begin{array}{ccc}
k & a & b \\
k & c & k \\
k & a & b \\
k & c & k
\end{array}
\]

Thus $\text{End}_B(N') = k$. Since a field is local we have that $N'$ is an indecomposable right $B$-module. It follows immediately that $N$ is also an indecomposable right $B$-module.

We have the projective $B$-presentation of $N$:

\[
e_4 B \xrightarrow{\phi'} e_4^* B \oplus e_2 B \longrightarrow N \longrightarrow 0
\]

This gives us the following matrix:

\[
\phi' = \begin{pmatrix}
\alpha_3 \\
\eta_2 \eta_3
\end{pmatrix}
\]

77
Thus $B[N]$ has quiver

\[
\begin{array}{cccccccc}
9 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\beta_1 & \alpha_1 & \beta_2 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & \eta_9
\end{array}
\]

with extra relation $\beta_1 \eta_2 \eta_3 + \beta_2 \alpha_3$. The new indecomposable projective module, $e_w B[N]$, has composition series shown below.

\[
\begin{array}{ccccccc}
& & & & & 2 & \\
& & & & w^* & & \\
& & & & & & 3 \\
& & & 6 & 7 & 4 & \\
& & 5 & 8 & 8 & 9 & \\
2 & 3 & 4 & 7 & 8 & 5 & 9
\end{array}
\]

Since the radical is indecomposable, and has the shape it does, we get that $B[N]$ is not isomorphic to a monomial algebra. A second application of Theorem 4.1.2 gives us $E(B[N])$ right Noetherian.

### 4.2 Triangular matrix algebras

We now present a generalisation of the work in the preceding chapter.

Following the notation of 3.1.1 we let $A = \begin{pmatrix} T & \tau M_U \\ 0 & U \end{pmatrix}$, be a triangular matrix algebra, where $T$ and $U$ are finite-dimensional algebras and $\tau M_U$ is a $T$-$U$-bimodule, finitely generated as a $T$-module and as a $U$-module.

We will show that, given certain conditions, properties of $E(A)$ can be inferred from properties of $E(T)$ and $E(U)$.

From [3] we have a description of the simple modules, projective modules and injective modules of $A$. Modules in the first row come from $C_A$, those in the second
from \( \tilde{C}_\lambda \).

<table>
<thead>
<tr>
<th>Simple Modules</th>
<th>Indecomposable Projective Modules</th>
<th>Indecomposable Injective Modules</th>
</tr>
</thead>
<tbody>
<tr>
<td>((S, 0, 0)) where ( S ) is a simple ( T )-module</td>
<td>((P, P \otimes_T M, 1_{R \otimes_T M})) where ( P ) is an indecomposable projective ( T )-module</td>
<td>((I, 0, 0)) where ( I ) is an indecomposable injective ( T )-module</td>
</tr>
<tr>
<td>((0, S', 0)) where ( S' ) is a simple ( U )-module</td>
<td>((0, Q, 0)) where ( Q ) is an indecomposable projective ( U )-module</td>
<td>((\text{Hom}_U(M, J), J, \phi)) where ( J ) is an indecomposable injective ( U )-module and ( \phi ) is some explicit map</td>
</tr>
</tbody>
</table>

Note that \( (A, B, f) \oplus (A', B', f') = (A \oplus A', B \oplus B', f \oplus f') \).

**Definition 4.2.1** Let \( R \) be a ring and \( A \) some \( R \)-module. Then we define \( \mathfrak{P}^R A \) to be the projective cover of \( A \) and \( \mathfrak{I}^R A \) to be the injective envelope of \( A \). More generally, let \( \mathfrak{P}^R_i A \) be the projective cover of the \( i \)-th syzygy in a minimal projective \( R \)-resolution of \( A \), and let \( \mathfrak{I}^R_i A \) be the injective envelope of the \( i \)-th cosyzygy in a minimal injective \( R \)-resolution of \( A \).

We now prove some results that will convenience us.

**Lemma 4.2.2** Let \( N \) be a finitely generated \( U \)-module and \( L \) be a finitely generated \( T \)-module. Then \( \mathfrak{P}^U(0, N, 0) = (0, \mathfrak{P}^U N, 0) \) and \( \mathfrak{I}^U(L, 0, 0) = (\mathfrak{I}^T L, 0, 0) \).

**Proof.** Let \( \mathfrak{P}^U N \xrightarrow{\pi} N \) be the projective cover of \( N \) in \( \text{mod-}U \). Then \((0, \mathfrak{P}^U N, 0)\) is a projective object in \( C_\lambda \). We consider the surjection \((0, \mathfrak{P}^U N, 0) \xrightarrow{(0, \pi)} (0, N, 0)\). Which we write in the following way:

\[
\begin{array}{cccc}
0 \otimes_T M & \xrightarrow{0} & 0 \otimes_T M & \xrightarrow{0} & 0 \otimes_T M \\
\downarrow 0 & & \downarrow 0 & & \downarrow 0 \\
\ker \pi & \xrightarrow{i} & \mathfrak{P}^U N & \xrightarrow{\pi} & N
\end{array}
\]

Since \( \ker \pi \) is superfluous in \( \mathfrak{P}^U N \) it is clear that \((0, \ker \pi, 0)\) is superfluous in \((0, \mathfrak{P}^U N, 0)\). Hence \((0, \mathfrak{P}^U N, 0)\) is the projective cover of \((0, N, 0)\) in \( C_\lambda \).

Now consider the \( T \)-module \( L \). Let \( L \xrightarrow{i} \mathfrak{I}^T L \) be the injective envelope of \( L \) in \( \text{mod-}T \). Then \((\mathfrak{I}^T L, 0, 0)\) is an injective object in \( C_\lambda \). We consider the injection
(L, 0, 0) \xrightarrow{(n, 0)} (3^TL, 0, 0). Which we write in the following way:

\[
\begin{array}{cccccc}
L & \xrightarrow{\eta} & \text{im} \eta & \xleftarrow{i} & 3^TL \\
0 & \downarrow & 0 & \downarrow & 0 \\
\text{Hom}_U(M, 0) & \xrightarrow{0} & \text{Hom}_U(M, 0) & \xrightarrow{0} & \text{Hom}_U(M, 0)
\end{array}
\]

Since im \( \eta \) is essential in \( 3^TL \) it is clear that \((\text{im} \eta, 0, 0)\) is essential in \((3^TL, 0, 0)\). Hence \((3^TL, 0, 0)\) is the injective envelope of \((L, 0, 0)\) in \( \tilde{C}_A \).

**Lemma 4.2.3** Let \( N \) and \( N' \) be right \( U \)-modules and let \( L \) and \( L' \) be right \( T \)-modules. Then

\[ \text{Hom}_A \left( (0, N, 0), (0, N', 0) \right) \cong \text{Hom}_U(N, N') \]

and

\[ \text{Hom}_A \left( (L, 0, 0), (L', 0, 0) \right) \cong \text{Hom}_T(L, L'). \]

**Proof.** We get isomorphisms:

\[
\begin{array}{cccccc}
N & \xrightarrow{\alpha} & N' & & \text{and} & L & \xrightarrow{\beta} & L' \\
0 \otimes_T M & \xrightarrow{0} & 0 \otimes_T M & & 0 \otimes_T M & \xrightarrow{0} & 0 \otimes_T M \\
N & \xrightarrow{\alpha} & N' & & \text{Hom}_U(M, 0) & \xrightarrow{0} & \text{Hom}_U(M, 0)
\end{array}
\]

Using the previous two lemmas we can give some identities. Let \( \cdots \rightarrow P_2 \rightarrow P_1 \rightarrow P_0 \) and \( I_0 \rightarrow I_{-1} \rightarrow I_{-2} \rightarrow \cdots \) be a minimal projective \( U \)-resolution of \( \bar{U} \) and a minimal injective \( T \)-resolution of \( \bar{T} \) (recall that for any algebra \( A \) with radical \( \mathfrak{r} \), we have \( \bar{A} = A/\mathfrak{r} \)). Then for all \( i \geq 0 \)

\[
\text{Ext}_A^i((\bar{T}, 0, 0), (\bar{T}, 0, 0))
\]

\[ \cong \text{Hom}_A((\bar{T}, 0, 0), \mathcal{J}^A_i(\bar{T}, 0, 0)) 
\]

\[ = \text{Hom}_A((\bar{T}, 0, 0), (I_{-1}, 0, 0)) 
\]

\[ \cong \text{Hom}_T(\bar{T}, I_{-1}) 
\]

\[ \cong \text{Ext}_T^i(\bar{T}, \bar{T}) 
\]
so we have an isomorphism of \( k \)-vector spaces \( v : \bigoplus_{n=0}^{\infty} \text{Ext}^n_A((T,0,0),(T,0,0)) \to E(T) \). In a similar way, we have

\[
\text{Ext}^n_A((0,\bar{U},0),(0,\bar{U},0)) \cong \text{Hom}_A(P^n,0,0)) \\
= \text{Hom}_A((0,P,0),(0,\bar{U},0)) \\
= \text{Hom}_U(P,\bar{U}) \\
= \text{Ext}^n_U(U,\bar{U})
\]

so \( \text{Ext}^*_A((0,\bar{U},0),(0,\bar{U},0)) \) is isomorphic as a \( k \)-vector space to \( E(U) \).

We also have that they are isomorphic as \( k \)-algebras by the following argument by E. L. Green.

**Lemma 4.2.4** The \( k \)-algebras \( \text{Ext}^*_A((T,0,0),(T,0,0)) \) and \( E(T) \) are isomorphic as rings, and the \( k \)-algebras \( \text{Ext}^*_A((0,\bar{U},0),(0,\bar{U},0)) \) and \( E(U) \) are isomorphic as rings.

**Proof (E. L. Green).** Recalling the descriptions of the indecomposable projective modules of \( \Lambda \), let

\[
\cdots \to (P_2, (P_2 \otimes M) \oplus Q_2, 1) \to (P_1, (P_1 \otimes M) \oplus Q_1, 1) \to (T, T \otimes M, 1)
\]

be a projective \( \Lambda \)-resolution of \((T,0,0)\). Write the \( n \)-th differential as:

\[
(P_n, (P_n \otimes M) \oplus Q_n, 1) \xrightarrow{(f_n, \delta_n)} (P_{n-1}, (P_{n-1} \otimes M) \oplus Q_{n-1}, 1)
\]

Note that \((P_*, f_*)\) is a projective \( T \)-resolution of \( \bar{T} \). Now let

\[
(\alpha, 0) : (P_n, (P_n \otimes M) \oplus Q_n, 1) \to (T, 0, 0)
\]

and

\[
(\beta, 0) : (P_m, (P_m \otimes M) \oplus Q_m, 1) \to (T, 0, 0)
\]

be arbitrary elements of \( \text{Ext}^*_{\Lambda}((T,0,0),(T,0,0)) \) and \( \text{Ext}^*_{\Lambda}((0,\bar{U},0),(0,\bar{U},0)) \) respectively. In order to multiply \((\alpha, 0)\) and \((\beta, 0)\), we lift \((\alpha, 0)\) in the usual way, to get

\[
(\alpha', \gamma) : (P_{n+m}, (P_{n+m} \otimes M) \oplus Q_{n+m}, 1) \to (P_m, (P_m \otimes M) \oplus Q_m, 1)
\]

Then we have \((\alpha', \beta, 0) = (\alpha', \gamma) \cdot (\beta, 0)\). Thus the product is exactly as if we had taken the product \( \alpha \beta \) in \( E(T) \).

Hence \( \text{Ext}^*_{\Lambda}((T,0,0),(T,0,0)) \) and \( E(T) \) are isomorphic as rings.

It is immediate that \( \text{Ext}^*_{\Lambda}((0,\bar{U},0),(0,\bar{U},0)) \) and \( E(U) \) are isomorphic as rings. □
Note that (as vector spaces)

$$\bigoplus_{i=0}^{\infty} \text{Ext}_A^i((0, \bar{U}, 0), (T, 0, 0)) = \bigoplus_{i=0}^{\infty} \text{Hom}_A((0, P_i, 0), (T, 0, 0)) = 0$$

by Lemma 4.2.3.

We thus have $E(A) \cong E(U) \oplus \text{Ext}_A^*((T, 0, 0), (0, \bar{U}, 0)) \oplus E(T)$. We now prove the first of our finiteness results. As demonstration to the necessity of the hypothesis, the reader is directed to Example 4.2.11.

**Theorem 4.2.5** Let $E(U)$ and $E(T)$ be right Noetherian rings and suppose that $\Omega^*_A(T, 0, 0) \cong (0, N, 0)$ for some finitely generated right $U$-module $N$ and some $n \geq 1$. Then $E(A)$ is a right Noetherian ring.

**Proof.** We will show that $E(A)$ is a Noetherian right $E(A)$-module. Let $V = E(U) \oplus \text{Ext}_A^*((T, 0, 0), (0, \bar{U}, 0))$, so that $E(A) \cong V \oplus E(T)$. It is clear that $V$ is a right $E(U)$-module. Now let $L = \bigoplus_{i=0}^{n-1} \text{Ext}_A^i((T, 0, 0), (0, \bar{U}, 0))$. Using Lemma 4.2.3, dimension-shifting and [6, 2.5.4] we have the following identity.

$$\text{Ext}_A^*(\bar{T}, 0, 0), (0, \bar{U}, 0))$$

$$\cong \bigoplus_{i=0}^{\infty} \text{Ext}_A^i((\bar{T}, 0, 0), (0, \bar{U}, 0))$$

$$\cong L \oplus \bigoplus_{i=n}^{\infty} \text{Ext}_A^i((\bar{T}, 0, 0), (0, \bar{U}, 0))$$

$$\cong L \oplus \bigoplus_{i=n}^{\infty} \text{Ext}_A^{i-n}(\Omega^*_A(T, 0, 0), (0, \bar{U}, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}_A^i(\Omega^*_A(T, 0, 0), (0, \bar{U}, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}_A^i((0, N, 0), (0, \bar{U}, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}_A^i(N, \bar{U})$$

$$\cong L \oplus \text{Ext}_T^*(N, \bar{U})$$

Note that $L$ is finite-dimensional by linearity of Hom and Schur's Lemma. By Proposition 4.1.1 we have that $\text{Ext}_T^*(N, \bar{U})$ is a finitely generated right $E(U)$-module. Since $L$ is finite-dimensional this means $L \oplus \text{Ext}_T^*(N, \bar{U})$ is a finitely generated right $E(U)$-module (note that we do not say $L$ is a right $E(U)$-module). Thus $V = E(U) \oplus L \oplus \text{Ext}_T^*(N, \bar{U})$ is a finitely generated right $E(U)$-module. Since $E(U)$ is a right Noetherian ring, $V$ is a Noetherian right $E(U)$-module. Now, since
the right action of \( \text{Hom}_A(T, T) \) is zero on \( V \), we get that \( V \) is a Noetherian right \((E(U) \oplus \text{Hom}_A(T, T))\)-module. However \( E(U) \oplus \text{Hom}_A(T, T) \) is a unital subring of \( E(\Lambda) \) and so \( V \) is a Noetherian right \( E(\Lambda) \)-module.

Now, by definition, \( E(T) \) is a Noetherian right \( E(T) \)-module. As the right action of \( \text{Hom}_A(U, U) \) is zero on \( E(T) \), we get that \( E(T) \) is a Noetherian right \((E(T) \oplus \text{Hom}_A(U, U))\)-module. However \( E(T) \oplus \text{Hom}_A(U, U) \) is a unital subring of \( E(\Lambda) \) and so \( E(T) \) is a Noetherian right \( E(\Lambda) \)-module. Hence \( E(\Lambda) = V \oplus E(T) \) is a Noetherian right \( E(\Lambda) \)-module and so \( E(\Lambda) \) is a right Noetherian ring. □

**Remark 4.2.6** It is important to note how Theorem 4.2.5 above is related to Theorem 4.1.2. For basic algebras it is in fact an encapsulation of what happens if one iterates Theorem 4.1.2. To explain, let \( U^0 \) be a finite-dimensional algebra with quiver \( Q^0 \) and with \( E(U^0) \) a right Noetherian ring, and let \( U^1 \) be a one-point extension of \( U^0 \). Then by Theorem 4.1.2, \( E(U^1) \) is a right Noetherian ring. Continuing this process, let \( U^{i+1} \) be a one-point extension of \( U^i \) and let \( U^i \) have quiver \( Q^i \), for \( i \geq 0 \). Then continued application of Theorem 4.1.2 says that \( E(U^i) \) is a right Noetherian ring for all \( i \geq 0 \). Consider now the quiver \( Q^i \) of \( U^i \) for some \( i \geq 1 \).

We have a copy of \( Q^0 \) inside that of \( Q^i \), but by the nature of a one-point extension there are no new oriented cycles in \( Q^i \): it contains only those found in \( Q^0 \). In this way it is clear that, for \( \Lambda := U^i \) and \( U := U^0 \), we fulfill the hypothesis in Theorem 4.2.5 which says that there must exist some \( n \geq 0 \) such that the composition series of the \( n \)-th syzygy \( \Omega^n_{U^i}(\overline{T}) \) contains only simple modules corresponding to vertices in \( Q^0 \), where \( \overline{T} \) is the direct sum of simple modules corresponding to the vertices of \( Q^i \) not in \( Q^0 \). In fact we must have \( n \leq i \). This puts \( \Omega^n_{U^i}(\overline{T}) \) in the image category of the functor \( \mathcal{F} \) of Section 3.2.

**Example 4.2.7** Consider the final algebra in Example 4.1.3, which here we will call \( \Lambda \). This has quiver

![Quiver Diagram](image)
and relations \( \eta_1 \eta_2 \eta_3, \eta_2 \eta_3 \eta_4 \eta_5, \eta_3 \eta_4 \eta_5 \eta_6, \eta_4 \eta_5 \eta_6 \eta_7 \eta_8 \eta_9, \eta_5 \eta_6 \eta_7 \eta_8 \eta_9 \eta_{10}, \alpha_3 \eta_4, \alpha_5 \eta_6 \eta_7 \eta_8 \eta_9, \alpha_6 \eta_7 \eta_8 \) and \( \beta_1 \eta_2 \eta_3 + \beta_2 \alpha_3 \). This is a triangular matrix algebra, where \( T \) is the algebra with quiver

\[
\begin{array}{c}
\eta_1 \\
\eta_2 \\
\eta_3 \\
\eta_4 \\
\eta_5 \\
\eta_6 \\
\eta_7 \\
\eta_8 \\
\eta_9 \\
\eta_{10}
\end{array}
\]

and no relations; where \( U \) is the algebra with quiver

\[
\begin{array}{c}
\eta_1 \\
\eta_2 \\
\eta_3 \\
\eta_4 \\
\eta_5 \\
\eta_6 \\
\eta_7 \\
\eta_8 \\
\eta_9 \\
\eta_{10}
\end{array}
\]

and relations \( \eta_1 \eta_2 \eta_3, \eta_2 \eta_3 \eta_4 \eta_5, \eta_3 \eta_4 \eta_5 \eta_6, \eta_4 \eta_5 \eta_6 \eta_7 \eta_8 \eta_9, \eta_5 \eta_6 \eta_7 \eta_8 \eta_9 \eta_{10}; \) and where \( M = (e_T \Lambda e_U), \) where \( e_T = e_{\nu^*} + e_{\omega^*} \) and \( e_U = e_1 + e_2 + \cdots + e_9. \)

Since \( T \) is hereditary, and \( U \) appears already in Example 2.5.6, we have that both \( E(T) \) and \( E(U) \) are right Noetherian rings. Further, the projective \( \Lambda \)-resolutions of \( S_{\nu^*} \) and \( S_{\omega^*} \) below show that there is some \( U \)-module \( N \) such that \( \Omega^A_{\Lambda}(T, 0, 0) = \Omega^A_{\Lambda}(U, 0, 0) = (0, N, 0), \) some \( n \geq 1. \)

\[
\cdots \rightarrow e_4 \Lambda \rightarrow e_{\nu^*} \Lambda \oplus e_2 \Lambda \rightarrow e_{\omega^*} \Lambda \rightarrow S_{\nu^*} \rightarrow 0
\]

\[
\cdots \rightarrow e_2 \Lambda \oplus e_4 \Lambda \oplus e_6 \Lambda \oplus e_7 \Lambda \rightarrow e_{\nu^*} \Lambda \rightarrow S_{\omega^*} \rightarrow 0
\]

We see that \( n = 2 \) in this case. Now we can use Theorem 4.2.5 to conclude that \( E(\Lambda) \) is right Noetherian.

To prove the companion to Theorem 4.2.5 we need the following companion to Proposition 4.1.1.

**Proposition 4.2.8** Let \( A \) be a finite-dimensional algebra with \( E(A) \) a left Noetherian ring and let \( B \) be a finitely generated right \( A \)-module. Then \( \text{Ext}^*_{\Lambda}(A/\ell, B) \) is a finitely generated left \( E(A) \)-module.
Proof. We first note that $\text{Ext}_A^*(A/r,B)$ is naturally a left $E(A)$-module. We show that it is finitely generated as a left $E(A)$-module by proceeding by induction on the radical length of $B$.

If $N$ is a finitely generated right $A$-module with $N_r = 0$ then $N$ is the direct sum of finitely many simple right $A$-modules. Therefore $\text{Ext}_A^*(A/r,N) \in \text{Add}^f(E(A)E(A))$, the category of finite sums of summands of the left regular $E(A)$-module. This means $\text{Ext}_A^*(A/r,N)$ is finitely generated as a left $E(A)$-module.

For the inductive hypothesis, suppose there exists some $n \geq 2$ such that if $N$ is a finitely generated right $A$-module with $N_{n-1} = 0$, then $\text{Ext}_A^*(A/r,N)$ is a finitely generated left $E(A)$-module.

For the inductive step suppose $N$ is some finitely generated $A$-module with $N_r = 0$. We form the short exact sequence

$$0 \rightarrow N_r \rightarrow N \rightarrow N/N_r \rightarrow 0$$

Applying the covariant functor $\text{Hom}_A(A/r,-)$ we get a long exact sequence in homology:

$$0 \rightarrow \text{Hom}_A(A/r,N_r) \rightarrow \text{Hom}(A/r,N) \rightarrow \text{Hom}(A/r,N/N_r)$$

which yields the exact sequence

$$\text{Ext}_A^*(A/r,N_r) \rightarrow \text{Ext}_A^*(A/r,N) \rightarrow \text{Ext}_A^*(A/r,N/N_r)$$

with $f_*$ and $g_*$ acting componentwise. For ease of notation let $R = E(A)$, $K = \text{Ext}_A^*(A/r,N_r)$, $L = \text{Ext}_A^*(A/r,N)$ and $Q = \text{Ext}_A^*(A/r,N/N_r)$. This gives us the exact sequence of $R$-modules

$$K \xrightarrow{f_*} L \xrightarrow{g_*} Q$$

from which we get the diagram

$$\begin{array}{cc}
K & \xrightarrow{f_*} & L & \xrightarrow{g_*} & Q \\
\downarrow{f_*} & & \downarrow{g_*} & & \downarrow{g_*} \\
\text{im } f_* & & \text{im } g_* & & \text{im } g_*
\end{array}$$
Since $\text{im } f_* = K/\ker f_*$ by the first isomorphism theorem, and $\ker g_* = \text{im } f_*$ by exactness, we have the short exact sequence

$$0 \longrightarrow K/\ker f_* \longrightarrow L \longrightarrow \text{im } g_* \longrightarrow 0$$

As $K$ is a finitely generated left $R$-module we have that $K/\ker f_*$ is a finitely generated left $R$-module and hence is Noetherian. Also $Q$ is a finitely generated left $R$-module and since $R$ is left Noetherian this means the submodule $\text{im } g_*$ is finitely generated and hence Noetherian. We now apply Proposition 3.3.1 to get $L$ Noetherian as a left $R$-module and hence finitely generated. Thus $\text{Ext}^*_A(A/T, N)$ is a finitely generated $E(A)$-module.

Hence by induction if $B$ is a finitely generated right $A$-module then $\text{Ext}^*_A(A/T, B)$ is a finitely generated left $E(A)$-module. □

We can now prove the companion to Theorem 4.2.5.

**Theorem 4.2.9** Let $E(U)$ and $E(T)$ be left Noetherian rings and suppose that $\Omega^\Lambda_n(0, U, 0) = (N', 0, 0)$ for some finitely generated right $T$-module $N'$ and some $n \geq 1$. Then $E(\Lambda)$ is a left Noetherian ring.

**Proof.** We will show that $E(\Lambda)$ is a Noetherian left $E(A)$-module. Let $W = \text{Ext}^*_A((T, 0, 0), (0, U, 0)) \oplus E(T)$, so that $E(\Lambda) = E(U) \oplus W$. It is clear that $W$ is a left $E(T)$-module. Now let $L = \bigoplus_{n=0}^{\infty} \text{Ext}^*_A((\hat{T}, 0, 0), (0, U, 0))$. Using Lemma 4.2.3, dimension-shifting and [6, 2.5.4] we have the following identity.

$$\text{Ext}^*_A((\hat{T}, 0, 0), (0, U, 0))$$

$$\cong \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, 0, 0), (0, U, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, 0, 0), (0, U, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, 0, 0), \Omega^\Lambda_n(0, U, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, 0, 0), \Omega^\Lambda_n(0, U, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, 0, 0), (N', 0, 0))$$

$$\cong L \oplus \bigoplus_{i=0}^{\infty} \text{Ext}^i_A((\hat{T}, N'))$$

$$\cong L \oplus \text{Ext}^*_A(\hat{T}, N')$$
Note that $L$ is finite-dimensional by linearity of Hom and Schur's Lemma. By Proposition 4.2.8 we have that $\text{Ext}^\bullet_T(T, N')$ is a finitely generated left $E(T)$-module. Since $L$ is finite-dimensional this means $L \oplus \text{Ext}^\bullet_T(T, N')$ is a finitely generated left $E(T)$-module (note that we do not say $L$ is a left $E(T)$-module). Thus $W = L \oplus \text{Ext}^\bullet_T(T, N') \oplus E(T)$ is a finitely generated left $E(T)$-module. Since $E(T)$ is a left Noetherian ring, $W$ is a Noetherian left $E(T)$-module. Now, since the left action of $\text{Hom}_A(\tilde{U}, \tilde{U})$ is zero on $W$, we get that $W$ is a Noetherian left $(E(T) \oplus \text{Hom}_A(\tilde{U}, \tilde{U}))$-module. However $E(T) \oplus \text{Hom}_A(\tilde{U}, \tilde{U})$ is a unital subring of $E(A)$ and so $W$ is a Noetherian left $E(A)$-module.

Now, by definition, $E(U)$ is a Noetherian left $E(U)$-module. As the left action of $\text{Hom}_A(T', T)$ is zero on $E(U)$, we get that $E(U)$ is a Noetherian left $(E(U) \oplus \text{Hom}_A(T', T))$-module. However $E(U) \oplus \text{Hom}_A(T', T)$ is a unital subring of $E(A)$ and so $E(U)$ is a Noetherian left $E(A)$-module. Hence $E(A) = E(U) \oplus W$ is a Noetherian left $E(A)$-module and so $E(A)$ is a left Noetherian ring. □

In the following example, $E(A)$ is left Noetherian but not right Noetherian, whereas $E(U)$ and $E(T)$ are both right and left Noetherian. To see that $E(A)$ is not right Noetherian, we need only consider that it has a basis element (maximal overlap sequence) of the form $c l \eta_1 \eta_2 \eta_3$ for each $l \geq 0$, where $c = \eta_1 \eta_2 \eta_3 \eta_4 \eta_5 \eta_6 \eta_7 \eta_8 \eta_9$. These elements can now be used to construct an ascending sequence of right ideals exactly as in the proof of Theorem 2.5.1.

**Example 4.2.10** Let $A$ be the finite-dimensional $k$-algebra with quiver

![Quiver Diagram](image-url)
and relations \( \eta_1 \eta_2 \eta_3, \eta_2 \eta_3 \eta_4 \eta_5, \eta_3 \eta_4 \eta_5 \eta_6, \eta_4 \eta_5 \eta_6 \eta_7 \eta_8, \eta_5 \eta_6 \eta_7 \eta_8 \eta_9, \eta_6 \eta_7 \eta_8 \eta_9 \eta_1, \eta_7 \eta_8 \eta_9 \eta_1, \) and \( \eta_4 \eta_5 \alpha_6 \beta_3. \)

This is a triangular matrix algebra, where \( T \) is the algebra with quiver:

![Triangular Matrix Algebra Diagram](image)

and relations \( \eta_1 \eta_2 \eta_3, \eta_2 \eta_3 \eta_4 \eta_5, \eta_3 \eta_4 \eta_5 \eta_6, \eta_4 \eta_5 \eta_6 \eta_7 \eta_8, \eta_5 \eta_6 \eta_7 \eta_8 \eta_9, \eta_6 \eta_7 \eta_8 \eta_9 \eta_1; \) where \( U \) is the algebra with two-component quiver:

\[
\begin{array}{c}
w^* \\
\beta_3 \\
x
\end{array}
\]

and no relations; and where \( M = (e_T A e_U), \) where \( e_T = e_1 + e_2 + \cdots + e_g \) and \( e_U = e_{w^*} + e_{w^*} + e_x. \)

Since \( T \) appears already in Example 2.5.6, and \( U \) is hereditary, we have that both \( E(T) \) and \( E(U) \) are left Noetherian rings. Further, the injective \( A \)-resolutions of \( S_{w^*}, \) \( S_{v^*} \) and \( S_x \) below show that there is some \( T \)-module \( N' \) such that \( \Omega_A^n(0, \tilde{U}, 0) = (N', 0, 0), \) some \( n \geq 1. \) We denote as \( I_a \) the injective \( A \)-module with simple socle \( S_a. \)

\[
\begin{align*}
0 & \rightarrow S_x \rightarrow I_x \rightarrow I_3 \rightarrow \cdots \\
0 & \rightarrow S_{v^*} \rightarrow I_{v^*} \rightarrow I_2 \oplus I_4 \oplus I_6 \oplus I_7 \rightarrow \cdots \\
0 & \rightarrow S_{w^*} \rightarrow I_{w^*} \rightarrow I_2 \oplus I_{v^*} \rightarrow I_4 \rightarrow \cdots
\end{align*}
\]

We see that \( n = 2 \) in this case. Now we can use Theorem 4.2.9 to conclude that \( E(A) \) is left Noetherian.

We now present an example demonstrating that the hypothesis in Theorem 4.2.5:

\[
\Omega_A^n(T, 0, 0) = (0, N, 0) \text{ for some finitely generated right } U\text{-module } N \text{ and some } n \geq 1
\]

cannot be removed.
Example 4.2.11 Let $Q$ be the quiver

$$
1 \xrightarrow{\alpha} 2 \\
\eta \\
3 \xrightarrow{\gamma} 4
$$

and form the path algebra $kQ$. Let $I = \langle (a/3)^2, \alpha \beta \eta \gamma \delta, (\gamma \delta)^2 \rangle$ be a two-sided ideal of $kQ$ and let $\Lambda = kQ/I$. Then $\Lambda$ is a triangular matrix $k$-algebra where

$T$ has quiver

$$
1 \xrightarrow{\alpha} 2
$$

with relation $(\alpha \beta)^2$

$U$ has quiver

$$
3 \xrightarrow{\gamma} 4
$$

with relation $(\gamma \delta)^2$

and $M = (e_1 + e_2)\Lambda(e_3 + e_4)$. Since $\Lambda$ is a monomial algebra we may use (left) maximal overlap sequences to calculate $E(\Lambda)$, $E(U)$ and $E(T)$. By Theorem 2.5.1 $E(T)$ and $E(U)$ are Noetherian. We get infinitely many basis elements in $\text{Ext}_A^*(\langle \tilde{T}, 0, 0 \rangle, \langle 0, \tilde{U}, 0 \rangle)$ of the form

$$
\begin{array}{c}
(\alpha \beta)^2 \\
(\alpha \beta)^2 \\
\vdots \\
(\alpha \beta)^2 \\
(\alpha \beta)^2 \\
(\gamma \delta)^2 \\
(\gamma \delta)^2 \\
\vdots \\
(\gamma \delta)^2 \\
(\gamma \delta)^2
\end{array}
$$

Now, $\text{Ext}_A^*(\langle \tilde{T}, 0, 0 \rangle, \langle 0, \tilde{U}, 0 \rangle)$ is a right $E(\Lambda)$-submodule of $E(\Lambda)$. Right multiplication of an element of the above form can only concatenate more of the relation $(\gamma \delta)^2$ on the right. Thus we need infinitely many elements to generate $\text{Ext}_A^*(\langle \tilde{T}, 0, 0 \rangle, \langle 0, \tilde{U}, 0 \rangle)$ as a right $E(\Lambda)$-module. Thus $E(\Lambda)$ has an infinitely generated right submodule and so is not a right Noetherian ring.

In summary of this and the previous chapter, we have seen in Theorems 4.2.5 and 4.2.9 how a Noetherian property shared by $E(U)$ and $E(T)$ is, under the right conditions, transferred to $E(\Lambda)$. The penalty we have had to impose in each case is that, for some finite $n$, respectively the $n$-th syzygy or $n$-th cosyzygy of a certain semi-simple module is well-behaved. In the context of transferring finiteness conditions, such a penalty perhaps should not come as a surprise. Indeed, in Example 4.2.11 we see that it is necessary.
Chapter 5

Summary and further study

This thesis has set out with the following problem in mind:

When is the Ext-algebra of a ring finitely generated or Noetherian?

The problem is vast in scope, which no one researcher could hope to answer with a lifetime's study, let alone complete in a single thesis. The rather more realistic goal for this thesis has been to answer as much of the above question, and in as much variety, as time allows. In this, success has been three-fold. Firstly, we have completely solved the problem for an important class of finite-dimensional algebras: the cycle algebras. From previous work by Green and Zacharia [18] this has led to a partial answer for all monomial algebras. Secondly, we have related the Ext-algebra of a triangular matrix algebra with the Ext-algebras of its two component algebras. Thus if one has smaller algebras with the above question answered, these results can be used to answer, at least partially, the same question for a larger algebra constructed from them. This second part of the thesis has quite a different philosophy from the first, and this is our second success. Finally, the thesis is not two divided halves, but two united parts. Whereas each part can stand alone, and they will be published as such in due course, the two parts complement each other, just as do the two philosophies. That is: prove directly for some class of algebra, then prove comparison results to construct many new examples from your original class.

A number of continuations of this project come to mind, although in some ways (happy ones I hope!) this chapter is a victim of the project's success. In the first part of the thesis we have used the smo-tube and a description of the Ext-algebra of a monomial algebra to classify the Ext-algebras of the class of cycle algebras.
Since this classification was complete, we must ask now whether our methods can be
generalised to a different or wider class. It is difficult to see how we could easily adapt
this work to solving directly our problem for any class of non-monomial algebras.
There is still some work left to be done in the monomial case, however: answering
the question raised by the (now known to be) false direction of the Green-Zacharia
proposition, which we have treated in Section 1.2. That is, solving the problem
of when the Ext-algebra of an arbitrary monomial algebra is finitely generated or
Noetherian. This will require some new ideas, not just adaptations of the material
presented here. One approach might be comparing the Auslander-Reiten quiver of
a cycle algebra to the finiteness condition of its Ext-algebra given in this thesis. The
Auslander-Reiten quiver of a cycle algebra has a natural shape to it, and there is a
result by Dag Madsen that suggests some link between the shape of the Auslander-
Reiten quiver and finiteness conditions of its Ext-algebra.

A different and exciting direction for the study of finiteness conditions of the Ext-
algebra is the study of $A_\infty$-algebras. The Ext-algebra has a natural $A_\infty$-structure
(this consists of a set of “higher homotopy” products), and so can be considered as
an $A_\infty$-algebra. It should be interesting to study the $A_\infty$-structure to see if there is
any bearing on whether the Ext-algebra is finitely generated or Noetherian.

For the second part of the thesis we can depart from the main problem alto­
gether. We showed in Section 4.2 that the two theorems presented there, were all
that could be hoped for from the triangular matrix construction (which is a gener­
alisation of the one-point extension). However, the Hochschild cohomology ring is
very closely related to the Ext-algebra. It should be that some of the results can be
adapted to produce, or at least inspire, similar comparison results for the Hochschild
cohomology ring of an algebra.
