Estimation of Heterogeneous Panels with Structural Breaks*

Badi H. Baltagi† Qu Feng‡ Chihwa Kao§

March 4, 2015

Abstract

This paper extends Pesaran’s (2006) work on common correlated effects (CCE) estimators for large heterogeneous panels with a general multifactor error structure by allowing for unknown common structural breaks. Structural breaks due to new policy implementation or major technological shocks, are more likely to occur over a longer time span. Consequently, ignoring structural breaks may lead to inconsistent estimation and invalid inference. We propose a general framework that includes heterogeneous panel data models and structural break models as special cases. The least squares method proposed by Bai (1997a, 2010) is applied to estimate the common change points, and the consistency of the estimated change points is established. We find that the CCE estimator have the same asymptotic distribution as if the true change points were known. Additionally, Monte Carlo simulations are used to verify the main results of this paper.

Keywords: Heterogeneous Panels, Cross-sectional Dependence, Structural Breaks, Common Correlated Effects.

1 Introduction

For panel data models, the presence of cross-sectional dependence due to unobservable common factors or spatial spillover effect is a major concern in estimation and inference. It could lead to invalid inference and inconsistent estimators, see Lee (2002) and Andrews (2005).\(^1\) Several tests for cross-sectional dependence in panel data models have been proposed in the literature. These include Pesaran (2004, 2012), Ng (2006), Pesaran, Ullah and Yamagata (2008), Sarafidis, Yamagata and Robertson (2009), Chen, Gao and Li (2011), Hsiao, Pesaran and Pick (2012), Baltagi, Feng and Kao (2011, 2012), Halunga, Orme and Yamagata (2011), Juhl (2011), and Su and Zhang (2011), to mention a few. To deal with cross-sectional dependence in panels, two general estimation methods have been proposed including spatial estimation methods (Anselin, 1988; Kelejian and Prucha, 1999; Kapoor, Kelejian and Prucha, 2007; Lee, 2007 and Lee and Yu, 2010, to name a few), and factor models (see Pesaran, 2006; and Bai, 2009, to name a few).

In particular, Pesaran (2006) develops common correlated effects (CCE) estimators for large heterogeneous panels with a general multifactor error structure by least squares using augmented data. The common correlated effects (factors) can be asymptotically partialled out by means of the cross-sectional average of the dependent variable and the individual-specific regressors when the cross-section dimension is large. Kapetanios, Pesaran and Yamagata (2011) show that the CCE estimator can be extended to the case of nonstationary unobserved common factors. Additionally, the CCE approach is also shown to be applicable to situations of spatial and other forms of weak cross-sectional dependent errors (Pesaran and Tosetti, 2011; Chudik, Pesaran and Tosetti, 2011), and heterogenous dynamic panel data models with weakly exogenous regressors (Chudik and Pesaran, 2013).\(^2\)

However, this literature assumes that the slope coefficients are constant over time. This implicit assumption is common in the literature on panel data models with large time dimension, see for example, Kao (1999), Phillips and Moon (1999), Hahn and Kuersteiner (2002), Alvarez and Arellano (2003), Phillips and Sul (2007), Pesaran and Yamagata (2008), Hayakawa (2009), to name a few. Due to policy implementation or technological shocks,

---

\(^1\) Baltagi and Pirotte (2010) show that tests of hypotheses based on standard panel data estimators that ignore spatial dependence lead to misleading inference.

\(^2\) In a panel with unobserved common factors, Banerjee and Carrion-i-Silvestre (2011) suggest a test for panel cointegration based on a pooled CCE estimator of the coefficients.
structural breaks are possible especially for panels with a long time span. Consequently, ignoring structural breaks may lead to inconsistent estimation and invalid inference.

This paper extends Pesaran’s (2006) heterogeneous panels by allowing for unknown common structural breaks in the slopes. This is useful for example when global technological or financial shocks affect all markets or firms at the same time. Since the framework of heterogeneous panels is fairly general and includes popular panel data models as special cases, it allows us to examine the issue of structural breaks in panel data models in a less restrictive way.

By considering both cross-sectional dependence and structural breaks in a general panel data model, this paper also contributes to the change point literature in several ways. First, it extends Bai’s (1997a) time series regression model to heterogeneous panels, showing that the consistency of estimated change points can be achieved with the information along the cross-sectional dimension. This result confirms the findings of Bai (2010) and Kim (2011). Second, it also enriches the analysis of common breaks of Bai (2010) and Kim (2011) in a panel mean-shift model and a panel deterministic time trend model by extending them to a regression model using panel data. This makes it possible to allow for structural breaks and cross-sectional dependence in empirical work using panel regressions. In particular, our methods can be applied to regression models using large stationary panel data, such as country-level panels and state/provincial-level panels.3

Regarding estimating common breaks in panels, Feng, Kao and Lazarova (2009) and Baltagi, Kao and Liu (2012) also show the consistency of the estimated change point in a simple panel regression model. Hsu and Lin (2012) examine the consistency properties of the change point estimators for nonstationary panels. More recently, Qian and Su (2014) and Li, Qian and Su (2014) study the estimation and inference of common breaks in panel data models with and without interactive fixed effects using Lasso-type methods. In terms of detecting structural breaks in panels, some recent literature includes Horváth and Hušková (2012) in a panel mean shift model with and without cross-sectional dependence, De Wachter and Tzavalis (2012) in dynamic panels, and Pauwels, Chan and Mancini-Griffoli (2012) in heterogeneous panels, to name a few.

The paper is organized as follows. Section 2 introduces heterogeneous panels with a

3Some empirical examples include Fleisher, Li and Zhao (2010) using Chinese provincial-level panel data, and Huang (2009) using country-level panels, to mention a few.
common structural break. Section 3 starts with a simple heterogeneous panel model that ignores the unobservable common correlated effects. This model can be regarded as a direct extension of Bai’s (1997a) time series regression model to a panel setup. The least squares estimation proposed by Bai (1997a) is applied. With the main results established in Section 3, the discussion of the general model with common correlated effects is presented in Section 4. Section 5 briefly discusses the case of multiple common breaks. In Section 6, Monte Carlo simulations are used to verify the consistency of the estimated common change point for both models considered. Section 7 provides concluding remarks. The mathematical proofs are relegated to the Appendix.

2 Heterogeneous Panels with a Common Structural Break

In a heterogeneous panel data model:

\[ y_{it} = x_{it}'\beta_i + e_{it}, \quad i = 1, ..., N; \quad t = 1, ..., T, \]

(1)

\[ x_{it} \] is a \( p \times 1 \) vector of explanatory variables, and the errors are cross-sectionally correlated, modelled by a multifactor structure

\[ e_{it} = \gamma_i' f_t + \varepsilon_{it}, \]

(2)

where \( f_t \) is an \( m \times 1 \) vector of unobserved factors and \( \gamma_i \) is the corresponding loading vector. \( \varepsilon_{it} \) is the idiosyncratic error independent of \( x_{it} \). However, \( x_{it} \) could be affected by the unobservable common effects \( f_t \). Projecting \( x_{it} \) on \( f_t \), we obtain

\[ x_{it} = \Gamma_i' f_t + v_{it}, \quad i = 1, ..., N; \quad t = 1, ..., T, \]

(3)

where \( \Gamma_i \) is an \( m \times p \) factor loading matrix. \( v_{it} \) is a \( p \times 1 \) vector of disturbances. Due to the correlation between \( x_{it} \) and \( e_{it} \), OLS for each individual regression could be inconsistent. Thus, Pesaran (2006) develops the CCE estimator of \( \beta_i \) by least squares using augmented data.\(^4\)

\(^4\)For simplicity, observed common effects like seasonal dummies are not included in (1), but they can be easily handled as in Pesaran (2006).
In this paper, we allow for structural breaks to occur in some or all components of the slopes \( \beta_i \).\(^5\) Following Bai (2010) and Kim (2011), a structural break at a common unknown date \( k_0 \) is assumed. This could be due to a macro policy implementation or a technological shock that affects all markets or firms at the same time. More formally,

\[
y_{it} = x_{it}'\beta_i(k_0) + e_{it}, \quad i = 1, ..., N; t = 1, ..., T, \tag{4}
\]

where some or all components of \( \beta_i(k_0) \) are different before and after the date \( k_0 \).\(^6\) Following Bai (1997a), this structural break model can be written as

\[
y_{it} = \begin{cases} x_{it}'\beta_i + e_{it}, & t = 1, ..., k_0, \\ x_{it}'\beta_i + z_{it}'\delta_i + e_{it}, & t = k_0 + 1, ..., T, \end{cases} \tag{5}
\]

\( i = 1, ..., N \), where \( z_{it} = R'x_{it} \) denotes a \( q \times 1 \) subvector of \( x_{it} \) with \( R' = (0_{q \times (p-q)}, I_q) \). \( I_q \) is the \( q \times q \) identity matrix with \( q \leq p \). The case where \( q < p \) denotes a partial change model, while the case where \( q = p \) is for a pure change model. Pauwels, Chan and Mancini-Griﬃoli (2012) propose a testing procedure for \( k_0 \) in this setting.

Substituting \( z_{it} = R'x_{it} \) in (5), we obtain

\[
\beta_i(k_0) = \beta_i + R\delta_i \cdot 1\{t > k_0\} = \begin{cases} \beta_{1i} = \beta_i, & t = 1, ..., k_0, \\ \beta_{2i} = \beta_i + R\delta_i, & t = k_0 + 1, ..., T, \end{cases}
\]

so that \( \beta_{2i} - \beta_{1i} = R\delta_i \), and \( \delta_i \) denotes the slope jump for \( i \). When \( \delta_i = 0 \) there is no structural break in the slope.

The case of multiple break points will be discussed in Section 5. In the next two sections, we consider the simple case of one common break as in model (5). Compared with the heterogeneous panel data model considered in Pesaran (2006), (5) has the extra component \( R\delta_i \cdot 1\{t > k_0\} \) in the slope, involving the unknown structural change point \( k_0 \). Thus, ignoring the structural break in the slopes may invalidate the CCE estimator proposed by

\(^6\)As shown in Section 4, to apply the CCE approach, the common break assumption is required. In Kim (2014), the common break assumption is generalized to handle heterogeneous responses to a common shock that follow a common distribution. Liao and Wang (2012) also assume a common distribution, instead of a common break date, and estimate individual-speciﬁc structural breaks and their cross-sectional distribution using Bayesian methods. In addition, Li, Chen and Gao (2011) consider a time-varying coeﬃcient panel data model where the slope coeﬃcient is allowed to be different for each time period, e.g., \( \beta(t) \), but common for all individuals.
Compared with the simple mean shift panel data model in Bai (2010), our model is enriched by adding a regression structure with $x_{it} \neq 1$ in general, as well as cross-sectional dependence characterized by a multifactor structure in the errors. When there are no unobservable common factors $f_t$, our model (4) can also be regarded as an extension of Bai (1997a) to a panel data setting. In addition, the model (4) above is similar to Kim (2011), who considered the case of a deterministic time trend with a common break.

Before proceeding to the general model (5), we start with a simple case of heterogeneous panels in the absence of common correlated effects $f_t$ in Section 3, and then extend the main results to the general case in Section 4.

To estimate the common change point $k_0$, we need the following additional assumptions:

**Assumption 1** $k_0 = \lceil \tau_0 T \rceil$, where $\tau_0 \in (0, 1)$ and $\lceil \cdot \rceil$ is the greatest integer function.

Note that unlike the time series model considered by Bai (1997a), the restriction of $\tau_0 \in (0, 1)$ is unnecessary in a panel mean shift setup considered by Bai (2010) as long as $T/N \to 0$. However, this assumption is required in our heterogeneous panels with general regressors. Enough observations are needed to consistently estimate the slopes in each regime.

Define $\phi_N = \sum_{i=1}^N \delta_i^T \delta_i$. For series $i$, $\delta_i^T \delta_i$ measures the magnitude of the structural break, thus $\phi_N$ is an indicator of the break magnitude for all $N$ series sharing a common break.

**Assumption 2** $\phi_N \to \infty$ and (i) $\frac{\phi_N}{N}$ is bounded as $N \to \infty$; (ii) $\frac{\phi_N}{N} \frac{T}{N} \to \infty$ and $\phi_N \frac{T}{N} \to \infty$ as $(N, T) \to \infty$.

$\delta_i$ could be random with a finite variance across $i$, with Assumption 2(i) describing this case. When $\delta_i$ is considered as random, Assumption 2 means that $\frac{\phi_N}{N}$ is stochastically bounded in part (i), and that $\frac{\phi_N}{N} \frac{T}{N}$ and $\frac{\sqrt{N}}{\phi_N \sqrt{T}}$ converge in probability to 0 in part (ii). Alternatively, $\delta_i$ could denote fixed parameters. Since Assumption 2(i) allows for the case where $\frac{\phi_N}{N} \to 0$ as $N \to \infty$, Assumption 2(ii) implies that it cannot converge to 0 too fast. Consequently, Assumption 2(i) imposes an upper bound on $\frac{\phi_N}{N}$, while Assumption 2(ii) imposes a lower bound on $\frac{\phi_N}{N}$.

---

7 As documented in the time series literature, e.g., Pesaran and Timmermann (2002), structural breaks could lead to forecast failure. Stock and Watson (2002, 2009) show that forecasts constructed using dynamic factor models are robust to small structural breaks of factor loadings. However, when the size of the break is big, ignoring structural breaks may yield biased and inconsistent forecasts, as illustrated by Banerjee, Marcellino and Masten (2008), Breitung and Eickmeier (2011), and Chen, Dolado and Gonzalo (2014).
In case $T$ grows at a comparable rate or faster than $N$, i.e., $T = O(N^\psi)$ with $\psi \geq 1$, Assumption 2(ii) implies that $\phi_N$ can diverge at any rate. When $\phi_N$ increases at a rate less than $N$, Assumption 2(ii) allows for the possibility of no structural break in some series.\(^8\)

### 3 Model 1: No Common Correlated Effects

In this section, we assume that there are no unobserved common effects $f_i$ in the errors and regressors. Or the loading vectors $\gamma_i$ and $\Gamma_i$ are equal to zero. For $i = 1, ..., N$,

$$y_{it} = \begin{cases} x_{it}' \beta_i + \varepsilon_{it}, & t = 1, ..., k_0, \\ x_{it}' \beta_i + z_{it}' \delta_i + \varepsilon_{it}, & t = k_0 + 1, ..., T. \end{cases} \tag{6}(6)$$

This is the special case of cross-sectionally independent errors, where a common break $k_0$ occurs in the heterogeneous slopes. This model generalizes Bai (1997a), Bai (2010) and Pesaran and Smith (1995). When $N = 1$, (6) is the time series model considered in Bai (1997a). When $x_{it} = 1$, this model reduces to the one in Bai (2010). In case the lagged dependent variable is included in $x_{it}$ and $\delta_i = 0$, (6) turns out to be the setup in Pesaran and Smith (1995).\(^9\)

**Assumption 3** (i) The disturbances $\varepsilon_{it}, i = 1, ..., N$, are cross-sectionally independent; (ii) For each series $i$, $\varepsilon_{it}$ is independent of $x_{it}$ for all $i$ and $t$; (iii) $\varepsilon_{it}$ is a stationary process with absolute summable autocovariances,

$$\varepsilon_{it} = \sum_{t=0}^{\infty} a_{it} \zeta_{i,t-t}$$

where $\{\zeta_{i,t}, t = 1, ..., T\}$ are independent and identically distributed (IID) random variables with finite fourth-order cumulants. Assume $0 < \text{Var}(\varepsilon_{it}) = \sum_{t=0}^{\infty} a_{it}^2 = \sigma_i^2 < \infty$. Also, for the $T \times 1$ vector $\varepsilon_i = (\varepsilon_{i1}, \varepsilon_{i2}, \cdots, \varepsilon_{iT})'$, $\text{Var}(\varepsilon_i) = \Sigma_{\varepsilon,i}$.

When $\varepsilon_{it}$ is serially uncorrelated, lagged dependent variables are predetermined and can be included as regressors in (6).

**Assumption 4** For $i = 1, ..., N$, the matrices $(1/j) \sum_{t=1}^{j} x_{it} x_{it}'$, $(1/j) \sum_{t=T-j+1}^{T} x_{it} x_{it}'$, $(1/j) \sum_{t=k_0-j+1}^{k_0+j} x_{it} x_{it}'$, and $(1/j) \sum_{t=k_0+1}^{T} x_{it} x_{it}'$ are stochastically bounded and have minimum

---

\(^8\)Assumption $\phi_N \to \infty$ rules out the case where there is no structural break in the slopes in all series.

\(^9\)Heterogeneous dynamic panel data models with weakly exogenous regressors and unobserved common factors are studied by Chudik and Pesaran (2013).
eigenvalues bounded away from zero in probability for all large \( j \). In addition, for each \( i \), \((1/T)\sum_{t=1}^{T} x_{it}x_{it}'\) converges in probability to a nonrandom and positive definite matrix as \( T \to \infty \).

This assumption is borrowed from Assumptions A3 and A4 in Bai (1997a).\(^{10}\) Its counterpart across the cross-sectional dimension is also needed.

**Assumption 5** For any positive finite integer \( s \), the matrices \( \frac{1}{N} \sum_{i=1}^{N} \sum_{t=k_{0}-s+1}^{k_{0}+s} x_{it}x_{it}' \) and \( \frac{1}{N} \sum_{i=1}^{N} \sum_{t=k_{0}+1}^{k_{0}+s} x_{it}x_{it}' \), \( i = 1, \ldots, N \), are stochastically bounded, with minimum eigenvalues bounded away from zero in probability for large \( N \). In addition, for each \( t \), \((1/N)\sum_{i=1}^{N} x_{it}x_{it}'\) is stochastically bounded as \( N \to \infty \).

**Assumption 6** \( \{\delta_{i}, i = 1, \ldots, N\} \) are drawn independently of \( \{x_{it}, i = 1, \ldots, N\} \).

Let \( b_{i} = (\beta_{i}', \delta_{i}')' \), \( i = 1, \ldots, N \), denote the slope parameters. In the random coefficient model considered by Pesaran and Smith (1995) and Pesaran (2006), we assume:

**Assumption 7** For \( i = 1, \ldots, N \),

\[
\begin{align*}
b_{i} &= b + v_{b,i}, v_{b,i} \sim IID(0, \Sigma_{b}), \tag{7}
\end{align*}
\]

where \( b = (\beta', \delta')' \), \( v_{b,i} = \left( \begin{array}{c} v_{\beta,i} \\ v_{\delta,i} \end{array} \right) \) and \( \Sigma_{b} = \left( \begin{array}{cc} \Sigma_{\beta} & 0 \\ 0 & \Sigma_{\delta} \end{array} \right) \) for \( i = 1, 2, \ldots, N \), where \( \|b\| < \infty \), \( \|\Sigma_{b}\| < \infty \), and the random deviations \( v_{b,i} \) are independent of \( x_{it} \) and \( \varepsilon_{jt} \) for all \( i, j \) and \( t \).

For any matrix or vector \( A \), the norm of \( A \) is defined as \( \|A\| = \sqrt{tr(AB')} \). This assumption is a simplified version of Assumption 4 of Pesaran (2006). Under Assumption 6, \( \{\delta_{i}, i = 1, \ldots, N\} \) are not necessarily random. When \( \{\delta_{i}, i = 1, \ldots, N\} \) are considered as random, as part of Assumption 7, Assumption 6 becomes redundant. Under Assumption 7, \( \Sigma_{\delta} \neq 0 \) implies a structural break in the slope.

By (4),

\[
y_{it} = x_{it}'\beta_{i} + x_{it}'R\delta_{i}1\{t > k_{0}\} + \varepsilon_{it},
\]

if the structural break is ignored, the term \( x_{it}'R\delta_{i}1\{t > k_{0}\} \) is absorbed in the error term \( \varepsilon_{it} = x_{it}'R\delta_{i}1\{t > k_{0}\} + \varepsilon_{it} \). This leads to inconsistency of OLS for each series due to endogeneity. Thus, estimating \( k_{0} \) first is essential.

\(^{10}\)As pointed out by Bai (1997a), Bai and Perron (1998, 2003) trending regressors are allowed in the form of \((t/T)'\), for \( l > 0 \), or any function of the time trend: \( g(t/T) \).
Let \( Y_i = (y_{i1}, \ldots, y_{iT})' \), \( X_i = (x_{i1}, \ldots, x_{iT})' \) and \( \varepsilon_i = (\varepsilon_{i1}, \varepsilon_{i2}, \ldots, \varepsilon_{iT})' \) denote the stacked data and errors for individual \( i = 1, \ldots, N \) over the time periods observed. Similarly, define \( Z_{0i} = (0, \ldots, 0, z_{i, k_0+1}, \ldots, z_{iT})' \). (6) can be written in matrix form as

\[
Y_i = X_i \beta_i + Z_{0i} \delta_i + \varepsilon_i, \quad i = 1, \ldots, N. \tag{8}
\]

The parameters of interest are \( \beta_i, \delta_i \) and the change point \( k_0 \). We first estimate \( k_0 \) using least squares as proposed by Bai (1997a, 2010). For any possible change point \( k = 1, \ldots, T - 1 \), define the matrices \( X_{2i}(k) = (0, \ldots, 0, x_{i, k+1}, \ldots, x_{iT})' \), and \( Z_{2i}(k) = (0, \ldots, 0, z_{i, k+1}, \ldots, z_{iT})' \). When \( k \) happens to be the true change point \( k_0 \), \( Z_{2i}(k_0) = Z_{0i} \). Define \( X_{0i} = X_{2i}(k_0) \), thus \( Z_{0i} = X_{0i} R \). To make the notation more compact, we let \( \bar{X}_i(k) = (X_i, Z_{2i}(k)) \) and \( \bar{X}_{0i} = (X_i, Z_{0i}) \). Thus, (8) becomes

\[
Y_i = X_i \beta_i + Z_{0i} \delta_i + \varepsilon_i = \bar{X}_{0i} b_i + \varepsilon_i, \quad i = 1, \ldots, N. \tag{9}
\]

Given any \( k = 1, \ldots, T - 1 \), one can estimate \( b_i \) by least squares,

\[
\hat{b}_i(k) = \begin{pmatrix} \hat{\beta}_i(k) \\ \hat{\delta}_i(k) \end{pmatrix} = [\bar{X}_i(k)' \bar{X}_i(k)]^{-1} \bar{X}_i(k)' Y_i, \quad i = 1, \ldots, N. \tag{10}
\]

The corresponding sum of squared residuals is given by

\[
SSR_i(k) = [Y_i - \bar{X}_i(k) \hat{b}_i(k)]'[Y_i - \bar{X}_i(k) \hat{b}_i(k)]
= [Y_i - X_i \hat{\beta}_i(k) - Z_{2i}(k) \hat{\delta}_i(k)]'[Y_i - X_i \hat{\beta}_i(k) - Z_{2i}(k) \hat{\delta}_i(k)],
\]

\( i = 1, \ldots, N \). Note that both \( \hat{b}_i(k) \) and \( SSR_i(k) \) depend on \( k \). For each series \( i \), \( k_0 \) can be estimated by \( \arg\min_{1 \leq k \leq T-1} SSR_i(k) \) as in Bai (1997a). Given that the structural break occurs at a common date for all cross-sectional units in the panel setup, the least squares estimator of \( k_0 \) is defined as

\[
\hat{k} = \arg\min_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i SSR_i(k). \tag{11}
\]

Weights \( \{\pi_i \in (0, 1), i = 1, \ldots, N; \sum_{i=1}^{N} \pi_i = 1\} \) allow for the possibility of different magnitudes, e.g., different variances, across series.

When \( N = 1 \), \( \hat{k} \) defined in (11) boils down to the change-point estimator considered by Bai (1997a) in a time series setting, with \( \hat{k} - k_0 = O_p(1) \) for large \( T \). In time series models, only the
break fraction $\tau_0 = k_0/T$, instead of $k_0$ itself, can be consistently estimated. In a multivariate time series set up, Bai, Lumsdaine and Stock (1998) show that the width of the confidence interval of the estimated change point decreases with the number of time series. This result implies that cross-sectional observations with common breaks improve the accuracy of the estimated change point. In fact, Bai (2010) shows that the least squares estimator of the change point is consistent in a panel mean-shift model, i.e., $\hat{k} - k_0 = o_p(1)$. A similar result is also obtained by Kim (2011) in a panel deterministic time trend model. In our heterogeneous panel regression model, (11) combines the information from each series by summing up $SSR_i(k)$. With a large $N$, $\hat{k}$ uses more information provided by the multiple time series sharing a common break. Consequently, the panel data estimator $\hat{k}$ is more accurate than the time-series estimator and achieves consistency, i.e., $\hat{k} - k_0 \xrightarrow{p} 0$ as $(N,T) \to \infty$.

**Theorem 1** Under Assumptions 1-6 (or 7), $\lim_{(N,T)\to\infty} P(\hat{k} = k_0) = 1$.

The proof of Theorem 1 can be found in the Appendix.

Given the estimated change point $\hat{k}$, the corresponding estimator of the slopes is $\hat{b}_i = \hat{b}_i(\hat{k})$, $i = 1, ..., N$. When $b_i$, $i = 1, ..., N$, are considered as random variables under Assumption 7, the cross-sectional mean $b$ can be consistently estimated by the mean group estimator proposed by Pesaran and Smith (1995) and Pesaran (2006):\(^{12}\)

$$\hat{b}_{MG} = \frac{1}{N} \sum_{i=1}^{N} \hat{b}_i = \frac{1}{N} \sum_{i=1}^{N} [X_i(\hat{k})'X_i(\hat{k})]^{-1}X_i(\hat{k})'Y_i. \quad (12)$$

### 4 Model 2: Common Correlated Effects

In this section, we extend Model 1 to the general model with common correlated effects (5):

for $i = 1, ..., N$,

$$y_{it} = x_{it}'\beta_i(k_0) + e_{it} = \left\{ \begin{array}{ll}
x_{it}'\beta_i + e_{it}, & t = 1, ..., k_0, \\
x_{it}'\beta_i + z_{it}'\delta_i + e_{it}, & t = k_0 + 1, ..., T.
\end{array} \right.$$  

where $e_{it} = \gamma_i'f_t + \varepsilon_{it}$. The regressors $x_{it}$, $i = 1, ..., N$, are allowed to be correlated with the unobservable factors $f_t$ modelled in (3), $x_{it} = \Gamma_i'f_t + v_{it}$. When $\delta_i = 0$, the model reduces to

\(^{11}\)Change-point estimators in the multivariate time series literature are discussed in Bai (2000) and Qu and Perron (2006).

\(^{12}\)Note that the pooled estimator of $b$ considered by Pesaran (2006) can be studied similarly. Since the asymptotic distributions of $\hat{b}_i$ and $\hat{b}_{MG}$ are similar to those derived in Bai (1997a) and Pesaran (2006), they are summarized in the Supplementary Appendix.
the one considered by Pesaran (2006). Kim (2011) considers the special case of \( x_{it} = (1,t)' \).\(^{13}\)

In this heterogeneous panel data model with a common break \( k_0 \), the parameters of interest are \( b_i = (\beta_i', \delta_i')' \), \( i = 1, ..., N \), and the change point \( k_0 \). The following assumptions are needed.

**Assumption 8** Common factors \( f_t, t = 1, ..., T \), are covariance stationary with absolute summable autocovariances, independent of errors \( \varepsilon_{is} \) and \( v_{is} \) for all \( i, s, t \).

**Assumption 9** Errors \( \varepsilon_{is} \) and \( v_{jt} \) are independent for all \( i, j, s, t \). \( v_{it} = \sum_{l=0}^{\infty} S_{il} v_{i,t-l} \), where \( (\zeta_{it}, v_{it}')' \) are \((p+1) \times 1\) vectors of IID random variables with variance-covariance matrix \( I_{p+1} \) and finite fourth-order cumulants, and

\[
\text{Var}(v_{it}) = \sum_{l=0}^{\infty} S_{il} S_{il}' = \Sigma_{i,v}, \text{ and } 0 < ||\Sigma_{i,v}|| < \infty.
\]

**Assumption 10** Factor loadings \( \gamma_i \) and \( \Gamma_i \) are IID across \( i \), and independent of \( \varepsilon_{jt}, v_{jt} \) and \( f_t \) for all \( i, j, t \). Assume \( \gamma_i = \gamma + \eta_i, \eta_i \sim IID(0, \Omega_\eta) \) and \( \Gamma_i = \Gamma + \xi_i, \xi_i \sim IID(0, \Omega_\xi) \), \( i = 1, ... N \), where the means \( \gamma, \Gamma \) are non-zero and fixed and the variances \( \Omega_\eta, \Omega_\xi \) are finite.

Together with Assumptions 3 and 7, Assumptions 8, 9 and 10 given above are the same as Assumptions 1-3 of Pesaran (2006), with the additional restrictions \( \gamma \neq 0 \) and \( \Gamma \neq 0 \).

The correlation between \( x_{it} \) and \( e_{it} \) due to unobserved common factors \( f_t \) renders OLS inconsistent. If \( f_t \) were observable, it could be treated as a regressor, and this correlation can be removed using a partitioned regression. Let \( F = (f_1, f_2, \cdots, f_T)' \), then the corresponding orthogonal projection matrix is given by \( M_f = I_T - F(F'F)^{-1}F' \). In this case, (5) can be written in matrix form as

\[
Y_i = X_i \beta_i + Z_{0i} \delta_i + F \gamma_i + \varepsilon_i, \quad i = 1, ..., N
\]

Premultiplying (13) by \( M_f \), we get

\[
\tilde{Y}_i = \tilde{X}_i \beta_i + \tilde{Z}_{0i} \delta_i + \tilde{\varepsilon}_i, \quad i = 1, ..., N,
\]

which is of the same form as equation (8) considered in Section 3, with transformed data \( \tilde{Y}_i = M_f Y_i, \tilde{X}_i = M_f X_i = M_f V_i, \tilde{Z}_{0i}(k_0) = M_f Z_{0i} \) and \( \tilde{\varepsilon}_i = M_f \varepsilon_i \). For each \( i = 1, ..., N \), the

\(^{13}\)In a similar panel set up without exogenous regressors, Bai and Carrion-i-Silvestre (2009) develop unit root tests applicable to situations of multiple structural breaks and unobserved common dynamic factors.
$T \times p$ vector $V_i$ denotes $(v_{i1}, ..., v_{iT})'$. Conditional on $F$, $(\tilde{X}_i, \tilde{Z}_0)$ and $\tilde{\varepsilon}_i$ are uncorrelated under Assumption 9.

However, $f_t$, $t = 1, ..., T$, are unobservable. To proceed, we follow Pesaran’s (2006) idea of using the cross-sectional averages of $y_{it}$ and $x_{it}$ as proxies for $f_t$. Combining (5) and (3) yields

$$w_{it} = \left( \begin{array}{c} y_{it} \\ x_{it} \end{array} \right) = C_{i}(k_0)' f_t + u_{it}(k_0),$$

where

$$C_{i}(k_0) = (\gamma_i, \Gamma_i) \begin{pmatrix} 1 \\ \beta_i(k_0) \end{pmatrix} \text{ and } u_{it}(k_0) = \begin{pmatrix} \varepsilon_{it} + v_{it}' \beta_i(k_0) \end{pmatrix}.$$ 

Note that like $\beta_i(k_0)$, the slope $C_i(k_0)$ in (15) also shifts at $k_0$.

$$C_i(k_0) = \left\{ \begin{array}{ll} C_{1i} = (\gamma_i + \Gamma_i \beta_{1i}, \Gamma_i), & t = 1, ..., k_0, \\ C_{2i} = (\gamma_i + \Gamma_i \beta_{2i}, \Gamma_i), & t = k_0 + 1, ..., T. \end{array} \right.$$ (16)

Common break $k_0$ splits the data generating process for all individuals into two regimes, and each regime has the same structure as that considered in Pesaran (2006). Consequently, unobserved common factors $f_t$ can be partialled out by using cross-sectional averages in the same spirit.

Let $\bar{w}_t = \sum_{i=1}^{N} \theta_i w_{it}$ be the cross-sectional averages of $w_{it}$ using weights $\theta_i$, $i = 1, ..., N$. In particular,

$$\bar{w}_t = \bar{C}(k_0)' f_t + \bar{u}_t(k_0)$$

where $\bar{C}(k_0) = \sum_{i=1}^{N} \theta_i C_{i}(k_0) = \left\{ \begin{array}{ll} \bar{C}_1 = \sum_{i=1}^{N} \theta_i C_{1i}, & t = 1, ..., k_0, \\ \bar{C}_2 = \sum_{i=1}^{N} \theta_i C_{2i}, & t = k_0 + 1, ..., T. \end{array} \right.$

The common break assumption is needed, otherwise $\bar{C}(k_0)$ is not well defined. $\bar{u}_t(k_0)$ is defined as

$$\bar{u}_t(k_0) = \sum_{i=1}^{N} \theta_i u_{it}(k_0) = \left\{ \begin{array}{ll} \bar{v}_t, & t = 1, ..., k_0, \\ \bar{v}_t + \sum_{i=1}^{N} \theta_i v_{it}' \beta_{1i} \end{array} \right., \quad \bar{v}_t + \sum_{i=1}^{N} \theta_i v_{it}' \beta_{2i} \right., & t = k_0 + 1, ..., T. \right.$$ (18)

As in Pesaran (2006), the weights $\theta_i$, $i = 1, ..., N$, satisfy conditions: $\theta_i = O(1/N)$, $\sum_{i=1}^{N} \theta_i = 1$ and $\sum_{i=1}^{N} |\theta_i| < \infty$.

**Assumption 11** \( \text{Rank}(\bar{C}_1) = \text{Rank}(\bar{C}_2) = m \leq p + 1. \)

11
We assume that rank condition is satisfied. Pesaran (2006) shows that in the case of deficient rank, it is impossible to obtain consistent estimators of the individual slope coefficients, but their cross-sectional mean can be consistently estimated. When \( \tilde{C}(k_0) \) is of full rank, \( f_t \) can be written as

\[
f_t = \left[ \tilde{C}(k_0)\tilde{C}(k_0)' \right]^{-1} \tilde{C}(k_0)(\tilde{w}_t - \tilde{u}_t(k_0)).
\]

From (16), the matrix \( \tilde{C}(k_0)\tilde{C}(k_0)' \) has two regimes, shifting at \( k_0 \),

\[
\tilde{C}(k_0)\tilde{C}(k_0)' = \left\{ \begin{array}{ll} C_1'C_1, & t = 1, \ldots, k_0, \\ C_2'C_2, & t = k_0 + 1, \ldots, T. \end{array} \right.
\]

Assumption 11 implies that \( \tilde{C}(k_0)\tilde{C}(k_0)' \) is invertible. As shown in Lemma 1 of Pesaran (2006), the cross-sectional average of the errors vanish in both regimes as \( N \to \infty \), where

\[
\tilde{\varepsilon}_t = \sum_{i=1}^{N} \theta_i \varepsilon_{it}, \quad \tilde{v}_t = \sum_{i=1}^{N} \theta_i v_{it}, \quad \text{yielding}
\]

\[
f_t - \left[ \tilde{C}(k_0)\tilde{C}(k_0)' \right]^{-1} \tilde{C}(k_0)\tilde{w}_t \overset{p}{\to} 0. \tag{19}
\]

This suggests that it is asymptotically valid to use \( \tilde{w}_t \) as observable proxies for \( f_t \). Let \( \tilde{W} = (\tilde{w}_1, \tilde{w}_2, \ldots, \tilde{w}_T)' \) denote the \( T \times (p+1) \) matrix of cross-sectional averages. Denote the \( T \times T \) matrix \( M_w \) by

\[
M_w = I_T - \tilde{W}(\tilde{W}'\tilde{W})^{-1}\tilde{W}'.
\]

Thus, similar to the result \( M_f F = 0 \), by (19) it is expected that the terms involving \( M_w \) are ignorable asymptotically as \( N \to \infty \).

Premultiplying (13) by \( M_w \) instead of \( M_f \), we obtain

\[
M_w Y_i = M_w X_i \beta_i + M_w Z_{0i} \delta_i + M_w F \gamma_i + M_w \varepsilon_i, \quad i = 1, \ldots, N. \tag{20}
\]

Let the \( T \times p \) matrix \( \tilde{X}_i = M_w X_i = (\tilde{x}_{i1}, \ldots, \tilde{x}_{iT})' \) denote the transformed regressors. Similarly, define \( \tilde{Y}_i = M_w Y_i, \tilde{Z}_{0i} = M_w Z_{0i} \) and \( \tilde{\varepsilon}_i = M_w \varepsilon_i \). Thus, (20) becomes

\[
\tilde{Y}_i = \tilde{X}_i \beta_i + \tilde{Z}_{0i} \delta_i + M_w F \gamma_i + \tilde{\varepsilon}_i = \tilde{X}_i \beta_i + \tilde{Z}_{0i} \delta_i + \tilde{\varepsilon}_i^0, \quad i = 1, \ldots, N, \tag{21}
\]

where \( \tilde{\varepsilon}_i^0 = M_w F \gamma_i + \tilde{\varepsilon}_i \).

Lemma 6 in the Appendix shows that each element of \( M_w F \gamma_i \) is of order \( O_p(\frac{1}{\sqrt{N}}) \) and vanishes as \( (N, T) \to \infty \), implying that \( \tilde{\varepsilon}_i^0 \) can be treated as \( \tilde{\varepsilon}_i \) asymptotically. Based on this intuition, we can follow the procedure proposed in Section 3 to estimate \( k_0 \) and \( b_i = (\beta_i', \delta_i')' \), using transformed data \( \{\tilde{Y}_i, \tilde{X}_i, i = 1, \ldots, N\} \).
For any possible change point \( k = 1, \ldots, T - 1 \), define matrices \( \tilde{Z}_2(k) = M_w Z_2(k) \), 
\( \tilde{X}_i(k) = (X_i, \tilde{Z}_2(k)) \) and \( \tilde{X}_{0i} = (\tilde{X}_i, \tilde{Z}_{0i}) \). With new notation, (21) becomes
\[
\tilde{Y}_i = \tilde{X}_{0i} b_i + \tilde{\varepsilon}_i^0, \ i = 1, \ldots, N. \tag{22}
\]

Given \( k \), slope \( b_i \) can be estimated by least squares,
\[
\tilde{b}_i(k) = \begin{pmatrix} \tilde{\beta}_i(k) \\ \tilde{\delta}_i(k) \end{pmatrix} = [\tilde{X}_i(k)\tilde{X}_i(k)]^{-1}\tilde{X}_i(k)'\tilde{Y}_i, \ i = 1, \ldots, N. \tag{23}
\]

The resulting sum of squared residuals is
\[
\tilde{SSR}_i(k) = [\tilde{Y}_i - \tilde{X}_i(k)\tilde{b}_i(k)]'[\tilde{Y}_i - \tilde{X}_i(k)\tilde{b}_i(k)]
= [\tilde{Y}_i - \tilde{X}_i\tilde{\beta}_i(k) - \tilde{Z}_2(k)\tilde{\delta}_i(k)]'[\tilde{Y}_i - \tilde{X}_i\tilde{\beta}_i(k) - \tilde{Z}_2(k)\tilde{\delta}_i(k)], \ i = 1, \ldots, N,
\]
and the estimator of \( k_0 \) is defined similarly as
\[
\tilde{k} = \arg\min_{1 \leq k \leq T-1} \sum_i \pi_i \tilde{SSR}_i(k), \tag{24}
\]
where \( \pi_i \) are weights, as in (11).

**Assumption 12** For \( i = 1, \ldots, N \), the matrices \( \frac{1}{T} X_i'M_w X_i \) and \( \frac{1}{T} X_i'M_j X_i \) are nonsingular, and their inverses have finite second-order moments.

This assumption of identifying \( b_i \) and \( b \) is adopted from Pesaran (2006).

Let \( \tilde{x}_{it} \) be the \( t \)th element of matrix \( \tilde{X}_i \), \( i = 1, \ldots, N \). To identify \( k_0 \), we need a modified version of Assumptions 4, 5, 6:

**Assumption 13** For \( i = 1, \ldots, N \), the matrices \( (1/j) \sum_{t=1}^j \tilde{x}_{it}\tilde{x}_{it}' \), \( (1/j) \sum_{t=j+1}^T \tilde{x}_{it}\tilde{x}_{it}' \), \( (1/j) \sum_{t=k_0-j+1}^{k_0} \tilde{x}_{it}\tilde{x}_{it}' \) and \( (1/j) \sum_{t=k_0+1}^{k_0+j} \tilde{x}_{it}\tilde{x}_{it}' \) are stochastically bounded and have minimum eigenvalues bounded away from zero in probability for all large \( j \). In addition, for each \( i \),
\[
(1/T) \sum_{t=1}^T \tilde{x}_{it}\tilde{x}_{it}' \text{ converges in probability to a nonrandom and positive definite matrix as } T \to \infty.
\]

**Assumption 14** For any positive finite integer \( s \), the matrices \( \frac{1}{N} \sum_{i=1}^N \sum_{t=k_0-s+1}^{k_0} \tilde{x}_{it}\tilde{x}_{it}' \) and \( \frac{1}{N} \sum_{i=1}^N \sum_{t=k_0+1}^{k_0+s} \tilde{x}_{it}\tilde{x}_{it}' \), \( i = 1, \ldots, N \), are stochastically bounded, with minimum eigenvalues bounded away from zero in probability for large \( N \). In addition, for each \( t \), \( (1/N) \sum_{i=1}^N \tilde{x}_{it}\tilde{x}_{it}' \) is stochastically bounded as \( N \to \infty \).
Assumption 15 \{\delta_i, i = 1, \ldots, N\} are drawn independently of the process of \{\bar{x}_{it}, i = 1, \ldots, N\}.

Alternatively, under a random coefficient model, we have a slightly different version of Assumption 7.

Assumption 16 For \(i = 1, \ldots, N\),

\[b_i = b + v_{b,i}, v_{b,i} \sim IID(0, \Sigma_b),\]

where \(b = (\beta', \delta')', v_{b,i} = \begin{pmatrix} v_{\beta,i} \\ v_{\delta,i} \end{pmatrix}\) and \(\Sigma_b = \begin{pmatrix} \Sigma_{\beta} & 0 \\ 0 & \Sigma_{\delta} \end{pmatrix}\) for \(i = 1, 2, \ldots, N\), where \(\|b\| < \infty\), \(\|\Sigma_b\| < \infty\), and the random deviations \(v_{b,i}\) are independent of \(\gamma_j, \Gamma_j, \varepsilon_{jt}\), and \(v_{jt}\) for all \(i, j\) and \(t\).

Under Assumption 16, \(b_i\) is independent of \(\Gamma_j\), implying that as \(N \to \infty\), \(C_1 = \sum_{i=1}^{N} \theta_i C_{1i} \xrightarrow{p} E(C_{1i}) = (\gamma + \Gamma \beta, \Gamma)\) and \(C_2 \xrightarrow{p} E(C_{2i}) = (\gamma + \Gamma (\beta + R\delta), \Gamma)\). In this case, rank condition Assumption 11 requires non-zero means for \(\gamma\) and \(\Gamma\) in Assumption 10 when \(N\) is large. Similarly in Model 1, When \(\{\delta_i, i = 1, \ldots, N\}\) are considered as random, as part of Assumption 16, Assumption 15 becomes redundant.

After the transformation (20), it can be shown that the change point estimator \(\tilde{k}\) is still consistent in a linear model with a multifactor error structure (5), i.e., \(\tilde{k} - k_0 = o_p(1)\).

Theorem 2 Under Assumptions 1-3, 8-15 (or 16), \(\lim_{(N,T) \to \infty} P(\tilde{k} = k_0) = 1\).

Theorem 2 can be proved similarly to Theorem 1, see the Appendix.

Given the change point estimator \(\tilde{k}\), the CCE estimator of the slope coefficients can be written as

\(\tilde{b}_i = \bar{b}_i(\tilde{k}) = [\tilde{X}_{i}(\tilde{k})'\tilde{X}_i(\tilde{k})]^{-1}\tilde{X}_i(\tilde{k})'\tilde{Y}_i, i = 1, \ldots, N.\)

Similar to Proposition 3, with the consistency of \(\tilde{k}\), the asymptotics of \(\tilde{b}_i\) can be established.

Proposition 1 Under Assumptions 1-3, 8-15, and \(\sqrt{T}/N \to 0\) as \((N, T) \to \infty\), for each \(i\),

\[\sqrt{T}(\tilde{b}_i - b_i) \xrightarrow{d} N \left(0, \Sigma_{\tilde{x}_i}^{-1}\Sigma_{\tilde{x}_i}^{-1}\Sigma_{\tilde{x}_i}^{-1}\right)\]

where

\(\Sigma_{\tilde{x}_i} = \text{plim}_{T \to \infty} \frac{1}{T} \tilde{X}_0'i\tilde{X}_0i\) and \(\Sigma_{\tilde{x}_i}^{-1} = \text{plim}_{T \to \infty} \frac{1}{T} \tilde{X}_0'i\Sigma_{\tilde{x}_i}^{-1}\tilde{X}_0i, i = 1, \ldots, N.\)
An additional condition $\sqrt{T}/N \to 0$ as $(N,T) \to \infty$ is required here, due to the fact that $M_w F \gamma_i$ is included in $\tilde{e}_i = M_w F \gamma_i + \tilde{e}_i$, the error term of transformed model (21) using cross-sectional averages. This yields an extra term in $\sqrt{T}(\hat{b}_i - b_i)$ whose order is $O_p(\sqrt{T}/N) + O_p(1/\sqrt{N})$ which is asymptotically ignorable when $\sqrt{T}/N \to 0$ as $(N,T) \to \infty$. See the Supplementary Appendix.

As discussed above, Assumption 2 allows that $T$ can grow faster than $N$, i.e., $T = O(N^\psi)$ with $\psi \geq 1$. Here, the relative speed of $N$ and $T$, $\sqrt{T}/N \to 0$ as $(N,T) \to \infty$ imposes an upper bound on $\psi$, i.e., $\psi < 2$. Therefore, in the case of $T = O(N^\psi)$ with $1 \leq \psi < 2$, both Assumption 2 and $\sqrt{T}/N \to 0$ as $(N,T) \to \infty$ required by Proposition 1 are satisfied.

As discussed by Pesaran (2006), a consistent Newey-West type estimator of $\Sigma_{\tilde{X}_{i},i}$ can be obtained using the transformed data,

$$
\tilde{\Sigma}_{\tilde{X}_{i},i} = \tilde{A}_{i0} + \sum_{j=1}^{\omega} (1 - \frac{j}{\omega + 1})(\tilde{A}_{ij} + \tilde{A}_{ij}'), \; \tilde{A}_{ij} = \frac{1}{T} \sum_{t=j+1}^{\omega} \tilde{e}_{it}\tilde{e}_{it-j}\tilde{X}_{it}(\tilde{k})\tilde{X}_{it}(\tilde{k})',
$$

where $\omega$ is the window size. $\tilde{e}_{it}$ is the $t^{th}$ element of $\tilde{e}_i = \tilde{Y}_i - \tilde{X}_i(\tilde{k})\tilde{b}_i$ and $\tilde{X}_{it}(\tilde{k})$ is the $t^{th}$ row of $\tilde{X}_i(\tilde{k})$. Since $\Sigma_{\tilde{X}_{i},i}$ can be consistently estimated by $\tilde{\Sigma}_{\tilde{X}_{i},i} = \tilde{\Sigma}_{\tilde{X}_{i},i}$, parameters $b_i, i = 1, \ldots, N$, in model (5) can be inferred as if $k_0$ were known.

The mean group estimator with a common break can be defined similarly:

$$
\tilde{b}_{MG} = \frac{1}{N} \sum_{i=1}^{N} \tilde{b}_i = \frac{1}{N} \sum_{i=1}^{N} [\tilde{X}_i(\tilde{k})'\tilde{X}_i(\tilde{k})]^{-1}\tilde{X}_i(\tilde{k})'\tilde{Y}_i.
$$

**Proposition 2** Under the assumptions 1-3, 8-14, 16,

$$
\sqrt{N}(\tilde{b}_{MG} - b) \xrightarrow{d} N(0, \Sigma_b).
$$

As in Pesaran (2006), $\Sigma_b$ can be consistently estimated by

$$
\frac{1}{N-1} \sum_{i=1}^{N} (\tilde{b}_i - \tilde{b}_{MG})(\tilde{b}_i - \tilde{b}_{MG})'.
$$
For detailed proofs of Propositions 1 and 2, see the Supplementary Appendix. Unlike Pesaran (2006), an additional step is needed, that of estimating $k_0$. As shown in the propositions above, with the consistency of $\tilde{k}$, the convergence rate of $\tilde{k}$ is not required for deriving the asymptotic distributions of $\tilde{b}_i$, for $i = 1, \ldots, N$, and $\tilde{b}_{MG}$.

5 Multiple Common Break Points

When multiple common break points, $k_0^{(1)}, \ldots, k_0^{(B_k)}$, occur in the slopes, there are $B_k + 1$ regimes for each individual:

$$y_{it} = \begin{cases} 
  x_{it}'\beta_i + e_{it}, & t = 1, \ldots, k_0^{(1)}, \\
  x_{it}'\beta_i + z_{it}'\delta_1i + e_{it}, & t = k_0^{(1)} + 1, \ldots, k_0^{(2)}, \\
  \vdots & \\
  x_{it}'\beta_i + z_{it}'\delta_{B_k,i} + e_{it}, & t = k_0^{(B_k)} + 1, \ldots, T,
\end{cases}$$

(27)

for $i = 1, \ldots, N$.

Estimation of multiple break points has been discussed by Bai (1997b) and Chong (1995) in a mean-shift model, Bai and Perron (1998) in linear regression models and Bai (2010) in a panel mean-shift model. To deal with this issue in model (27), we can follow the sequential or one at-a-time approach discussed by Bai (1997b, 2010). The number of common breaks, $B_k$, is assumed known. The idea of the sequential approach is to estimate break points one by one. For example, if $B_k = 3$, the estimation of $k_0^{(1)}, k_0^{(2)}$ and $k_0^{(3)}$ can be completed in 3 steps. In the first step, one break point is assumed as in Model 1 (or Model 2) above, and can be estimated by (11) (or (24)), denoted by $\hat{k}^{(1)}$ (or $\tilde{k}^{(1)}$). In the second step, in each of the two sub-panels split by $\hat{k}^{(1)}$ (or $\tilde{k}^{(1)}$), the same procedure (11) (or (24)) is applied. Thus, two single break estimators are obtained in these two sub-panels. $\hat{k}^{(2)}$ (or $\tilde{k}^{(2)}$) is defined as the one associated with a larger reduction in the sum of squared residuals. Similarly, $\hat{k}^{(1)}$ and $\hat{k}^{(2)}$ (or $\tilde{k}^{(1)}$ and $\tilde{k}^{(2)}$) yield 3 sub-panels. In the third step, in each of these 3 sub-panels, one break point can be estimated as in Section 3 (or 4). Among these 3 break estimators, we choose the one associated with the largest reduction of sum of squared residuals, denoted as $\hat{k}^{(3)}$ (or $\tilde{k}^{(3)}$). As suggested by Bai (2010), it can be shown that after rearranging $(\hat{k}^{(1)}, \hat{k}^{(2)}, \hat{k}^{(3)})$ (or

---

14In a time series regression model, a sup $F_T(l+1|l)$ test is proposed by Bai and Perron (1998) to determine the number of structure breaks. Bai and Perron (2003) report the simulation results of this test and compare it with other tests based on information criteria. A panel version of the sup $F_T(l+1|l)$ test can be applied to determine the number of common breaks in our setup.
\( (\hat{k}^{(1)}, \hat{k}^{(2)}, \hat{k}^{(3)}) \) in temporal order, \((\hat{k}^{(1)}, \hat{k}^{(2)}, \hat{k}^{(3)})\) (or \((\tilde{k}^{(1)}, \tilde{k}^{(2)}, \tilde{k}^{(3)})\) in Model 2) is consistent for \((k_0^{(1)}, k_0^{(2)}, k_0^{(3)})\) as long as the assumptions listed in Section 3 (or 4) hold in each of the sub-panels.

Once the consistent estimators of \((k_0^{(1)}, ..., k_0^{(B_k)})\) are obtained, the parameters \(\beta_i, \delta_{1i}, ..., \delta_{B_k,i}, \)
\(i = 1, ..., N,\) can be estimated by least squares as in (10) (or (23)). Thus, their mean-group estimators can be obtained similarly.

6 Monte Carlo Simulations

This section employs Monte Carlo simulations to examine the consistency of the estimated break points \(\hat{k}\) and \(\tilde{k}\) summarized in Theorems 1 and 2. Since the CCE estimators in Model 2 have the same asymptotic distributions as if the true common breaks were known, their asymptotic properties are not examined here. Two different designs are used for Models 1 and 2, respectively. In Model 1, there are no common correlated effects in the errors and regressors, so least squares can be run for each individual series. While in Model 2, the regressors and errors are correlated due to common correlated effects \(f_t.\) A transformation, using cross-sectional averages of the dependent variable and regressors proposed by Pesaran (2006), is needed to remove such effects asymptotically.

In the following experiments, the focus is on the histograms of \(\hat{k}\) and \(\tilde{k}\) in setups with different combinations of \((N,T).\)

6.1 Model 1: No common correlated effects

The data generating process of Model 1 is modified from that in Pesaran (2004, p.24):

\[
y_{it} = \alpha_i + \beta_i(k_0)y_{i,t-1} + e_{it}, i = 1, ..., N; t = 1, ..., T;
\]
\[
e_{it} = \gamma_i f_t + \epsilon_{it}.
\]

Here we set \(\gamma_i = 0,\) so there is no cross-sectional dependence in the errors. Instead, in this dynamic heterogeneous panel model, there is a common break \(k_0 = 0.5T\) in the slopes \(\beta_i,\)

for \(i = 1, ..., N,\) i.e.,

\[
\beta_i(k_0) = \begin{cases} 
\beta_{1i}, & t = 1, ..., k_0, \\
\beta_{2i} = \beta_{1i} + \delta_i, & t = k_0 + 1, ..., T,
\end{cases}
\]
where $\delta_i$ is the jump in the slope for each series. We assume $\beta_{1i} \sim iidU(0, 0.8)$ and $\delta_i \sim iidU(0, 0.2)$. We set $\alpha_i = \mu_i(1 - \beta_{1i})$, $\mu_i = \varepsilon_{0i} + \eta_i$ where $\varepsilon_{0i} \sim iidN(0, 1)$ and $\eta_i \sim iidN(1, 2)$. In addition, we assume $y_{i,0} \sim iidN(0,1)$ and $\varepsilon_{it} \sim iidN(0, \sigma_i^2)$, with $\sigma_i^2 \sim \chi^2/2$.

In (11), for any possible change point $k = 1, \ldots, T - 1$, the estimated change point $\hat{k}$ is the one that minimizes the sum of $N$ individual sum of squared residuals. 1000 replications are performed to obtain the histogram of $\hat{k}$ for each setup.

Figure 1 reports the histograms of $\hat{k}$ for $T = 20$ and $N = 1, 10, 50, 200$. It shows that the distribution of $\hat{k}$ shrinks with $N$. The frequency of choosing the true value $k_0$ increases from 8\% to 58\% when $N$ increases from 1 to 200. In case $T = 50$, as Figure 2 shows, the frequency of choosing the true value $k_0$ improves to almost 90\% for $N = 200$. This finding supports Theorem 1, confirming that multiple individual series provide additional information on $k_0$, and that $\hat{k}$ converges to $k_0$ as the number of series goes to infinity.

To consider the case where there is no structural break in slopes in some series, we set $\delta_i = 0$ in $[N/4]$ series, implying that $\phi_N$ increases with $N$ at a rate of $O(N^{3/4})$. Figure 3 reports the histograms of $\hat{k}$ for this case with $T = 50$. Similar to Figure 2, the pattern that $\hat{k}$ converges to $k_0$ as $N$ increases remains. However, the frequency of choosing the true value $k_0$ is significantly smaller than that in Figure 2. For example, for $N = 50$, the frequency of choosing the true value $k_0$ drops from 44\% in Figure 2 to 34\% in Figure 3. This suggests that for the accuracy of the estimated change point, allowing for no break in some series is equivalent to reducing the number of series or the magnitude of break $\phi_N$.

### 6.2 Model 2: Common correlated effects

The data generating process for Model 2 is as follows:

\[
y_{it} = \alpha_i + \beta_i(k_0)x_{i,t} + e_{it}, i = 1, \ldots, N; t = 1, \ldots, T
\]

\[
e_{it} = \gamma_{1i}f_i + \varepsilon_{it},
\]

where $\alpha_i \sim iidN(1,1)$ and $\gamma_{1i} \sim iidN(1,0.2)$. The idiosyncratic errors are generated as $\varepsilon_{it} \sim iidN(0, \sigma_i^2)$ and $\sigma_i^2 \sim iidU(0.5,1.5)$. There is a common break in the individual slopes:

\[
\beta_i(k_0) = \begin{cases} 
\beta_{1i}, & t = 1, \ldots, k_0, \\
\beta_{2i} = \beta_{1i} + \delta_i, & t = k_0 + 1, \ldots, T, \\
k_0 = 0.5T,
\end{cases}
\]

where $\beta_{1i} = 1 + \eta_i$, $\eta_i \sim iidN(0,0.04)$ and $\delta_i \sim iidN(0,0.04)$. 

18
Unlike Model 1, the error $e_{it}$ and the regressor $x_{it}$ contain the common correlated effect $f_t$:

\[ x_{it} = a_i + \gamma_{2i}f_t + v_{it}, \]

where $a_i \sim iidN(0.5, 0.5)$, $\gamma_{2i} \sim iidN(0.5, 0.5)$ and $v_{it} \sim iidN(0, 1 - \rho_{vi}^2)$, with $\rho_{vi} = 0.5$. The factor $f_t$ is generated by the stationary process:

\[ f_t = \rho_f f_{t-1} + v_{ft}, t = -49, \ldots, 0, 1, \ldots, T; \]
\[ \rho_f = 0.5, v_{ft} \sim iidN(0, 1 - \rho_f^2), f_{-50} = 0. \]

The correlation between $x_{it}$ and $e_{it}$ renders OLS inconsistent in the individual regressions. Thus, transformation (20) using cross-sectional averages of $y_{it}$ and $x_{it}$ is needed to remove $f_t$ before conducting least squares estimation of $k_0$.

The setup above is a simplified version of the design in Pesaran (2006). First, as in model (4), the observed factors are omitted for simplicity. Second, the number of regressors and unobservable factors are reduced to 1, respectively. Third, the correlation structures in $v_{it}$ and $\varepsilon_{it}$ are removed. The only new feature of this model is that there is a common break at $k_0$, specified as $0.5T$.

The first row of Figure 4 presents the histograms of the estimated change point $\tilde{k}$ for $T = 20$. It replicates the pattern in Figure 1, showing that after the transformation, the frequency of choosing the true value $k_0$ increases significantly with $N$. Figure 4 also reports, in the second row, the histograms of the estimated change point $\hat{k}$ without conducting transformation (20). It indicates that in the presence of common correlated effects, cross-sectional information using multiple series fails to improve the accuracy of the estimated change point.

Figures 5 and 6 report the histograms of $\tilde{k}$ and $\hat{k}$ for $T = 50$ and 200, respectively. The same pattern emerges, suggesting that the distribution of $\tilde{k}$ shrinks to $k_0$ as $N \to \infty$. Different from Figure 4, the frequency of $\hat{k}$, the estimator without conducting transformation (20), choosing the true break date increases with $N$ in Figure 6 when $T$ is large, although not at a rate as high as that of $\tilde{k}$ using the transformed data. Whether $|\hat{k} - k_0|$ shrinks to 0 or not as $(N, T) \to \infty$ depends upon the correlation between $x_{it}$ and $e_{it}$. In Figure 7, we increase this correlation by changing the distribution of $\gamma_{1i}$ from $N(1, 0.2)$ to $N(2, 0.2)$. In this case, the cross-sectional information using multiple series fails to improve the accuracy.

Note: The DGP is the same as in Figure 4, except that the correlation between $x_{it}$ and $e_{it}$ increases by changing the distribution of $\gamma_{it}$ from iid$N(1, 0.2)$ to iid$N(2, 0.2)$. $k_0 = 0.5T = 100$.  

26
of the estimated change point $\hat{k}$. This is consistent with the findings of Kim (2011).\textsuperscript{15}

7 Conclusion

The recent literature on panel data models with large time dimension assumes that the slopes are constant over time. However, due to global policy or technological shocks, slope parameters are likely to fall into different regimes over a longer time span. This paper tackles both structural breaks and cross-sectional dependence by extending Pesaran’s (2006) framework of heterogeneous panels to the situation of unknown common breaks in the slopes. The least squares method proposed by Bai (1997a, 2010) is applied to estimate the common change points. This method is married to the CCE estimators proposed by Pesaran (2006) in this setup. Different from the time series change point models, in which the estimated change point is inconsistent, our paper establishes its consistency in a general panel data setup. The properties of the CCE estimators of the slopes at estimated points are also examined. We find that the CCE estimators have the same asymptotic distributions as if the true change points were known.\textsuperscript{16}

In this paper, we assume that the rank condition is satisfied. In case of deficient rank, Westerlund and Urbain (2013) show that the CCE estimators could be inconsistent when factor loadings in the error term and in the explanatory variables are correlated. In this case, the iterative principal component approach, proposed by Bai (2009) in homogeneous panels and extended by Song (2012) to dynamic heterogeneous panels, can be an alternative, which allows for correlated and zero-mean factor loadings. However, the issue of structural breaks in this setup is beyond the scope of this paper.

\textsuperscript{15}Experiments with different values of parameters and distributions are conducted and similar histograms are obtained. Results are not included here to save space.

\textsuperscript{16}Since the convergence rate of the change point estimator is not required to derive the asymptotic distributions of the CCE estimators of slopes and their cross-sectional mean, we leave the derivations of convergence rate and asymptotic distribution of the change point estimator in heterogeneous panels for future research.
Appendix: Mathematical Proofs

Since the panel data model (6) considered here includes the time series model in Bai (1997a) as a special case of $N = 1$, it can be shown similarly that $\hat{k} - k_0 = O_p(1)$. In the proofs that follow, we assume $\hat{k} - k_0$ is stochastically bounded. With more information along the cross-sectional dimension under the common break assumption, we further show that $\hat{k} - k_0 \overset{p}{\to} 0$ as $(N, T) \to \infty$.

For $i = 1, ..., N$, let $SSR_i$ be the sum of squared residuals of regressing $Y_i$ on $X_i$ in case there is no break, i.e., $Z_{2i}(k) = 0_{T \times q}$. Using the identity

$$SSR_i - SSR_i(k) = [Y_i - X_i^{'}\hat{\beta}_i(k) - Z_{2i}(k)\hat{\delta}_i(k)][Y_i - X_i^{'}\hat{\beta}_i(k) - Z_{2i}(k)\hat{\delta}_i(k)]$$

$$= [Y_i - X_i^{'}\hat{\beta}_i(k)][Y_i - X_i^{'}\hat{\beta}_i(k)] = \hat{\delta}_i(k)'[Z_{2i}(k)'M_iZ_{2i}(k)]\hat{\delta}_i(k)$$

with $M_i = I - X_i(X_i^{'}X_i)^{-1}X_i^{'}$,

$$\hat{k} = \arg \min_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i SSR_i(k) = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i SV_i(k) = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i [SV_i(k) - SV_i(k_0)],$$

where $SV_i(k) = \hat{\delta}_i(k)'[Z_{2i}(k)'M_iZ_{2i}(k)]\hat{\delta}_i(k)$. Note that $SV_i(k_0) = \hat{\delta}_i(k_0)'[Z_{0i}'M_iZ_{0i}]\hat{\delta}_i(k_0)$ is not a function of $k$. For simplicity, we assume $\pi_i = 1/N$, $i = 1, ..., N$.

To prove Theorem 1, $\sum_{i=1}^{N} [SV_i(k) - SV_i(k_0)]$ can be decomposed into a deterministic part and a stochastic one. Partitioned regression gives

$$\hat{\delta}_i(k) = [Z_{2i}(k)'M_iZ_{2i}(k)]^{-1} Z_{2i}(k)'M_iY_i, \ i = 1, ..., N.$$

Substituting $Y_i = X_i\beta_i + Z_{0i}\delta_i + \varepsilon_i$ into the equation above, we obtain

$$\hat{\delta}_i(k) = [Z_{2i}(k)'M_iZ_{2i}(k)]^{-1} Z_{2i}(k)'M_iZ_{0i}\delta_i + [Z_{2i}(k)'M_iZ_{2i}(k)]^{-1} Z_{2i}(k)'M_i\varepsilon_i$$

and $\hat{\delta}_i(k_0) = \delta_i + (Z_{0i}'M_iZ_{0i})^{-1} Z_{0i}'M_i\varepsilon_i$.

\textsuperscript{17}Since the weights $\pi_i$, $i = 1, ..., N$, are used to balance different variances across series, we can always employ $\pi_i = 1/N$, $i = 1, ..., N$, by using different notations for $X_i$ and $\sigma_i^2$. 28
To simplify notation, $k$ is suppressed in $\hat{\delta}_i(k)$ and $Z_{2i}(k)$ when no confusion arises. Since

$$SV_i(k) = \delta_i' (Z_{2i}', M_i Z_{2i}) \hat{\delta}_i = \delta_i' (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} (Z_{2i}' M_i Z_{0i}) \delta_i$$

$$+ 2\delta_i' (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i + \varepsilon_i' M_i Z_{2i} (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i,$$

it follows that

$$SV_i(k) - SV_i(k_0) = -\delta_i' [(Z_{0i}', M_i Z_{0i}) - (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} (Z_{2i}' M_i Z_{0i})] \delta_i$$

$$+ 2\delta_i' (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i - 2\delta_i' Z_{0i}' M_i \varepsilon_i$$

$$+ \varepsilon_i' M_i Z_{2i} (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i - \varepsilon_i' M_i Z_{0i} (Z_{0i}' M_i Z_{0i})^{-1} Z_{0i}' M_i \varepsilon_i. \tag{28}$$

The deterministic part is denoted by

$$J_{1i}(k) = \delta_i' [(Z_{0i}', M_i Z_{0i}) - (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} (Z_{2i}' M_i Z_{0i})] \delta_i, \tag{31}$$

and the stochastic part is denoted by

$$J_{2i}(k) = 2\delta_i' (Z_{0i}', M_i Z_{2i}) (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i - 2\delta_i' Z_{0i}' M_i \varepsilon_i$$

$$+ \varepsilon_i' M_i Z_{2i} (Z_{2i}' M_i Z_{2i})^{-1} Z_{2i}' M_i \varepsilon_i - \varepsilon_i' M_i Z_{0i} (Z_{0i}' M_i Z_{0i})^{-1} Z_{0i}' M_i \varepsilon_i. \tag{30}$$

Thus $SV_i(k) - SV_i(k_0) = -J_{1i}(k) + J_{2i}(k)$ and

$$\hat{k} = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^{N} [SV_i(k) - SV_i(k_0)] = \arg \max_{1 \leq k \leq T-1} \left[ -\sum_{i=1}^{N} J_{1i}(k) + \sum_{i=1}^{N} J_{2i}(k) \right].$$

Define

$$X_{\Delta i} = X_{2i} - X_{0i} = (0, \cdots, 0, x_{i,k+1}, \cdots, x_{i,k_0}, 0, \cdots, 0)'$$

$$X_{\Delta i} = - (X_{2i} - X_{0i}) = (0, \cdots, 0, x_{i,k_0+1}, \cdots, x_{i,k}, 0, \cdots, 0)'$$

for $k < k_0,$

for $k \geq k_0.$

$Z_{\Delta i}$ can be defined similarly.

For a finite large number $C_k$ and arbitrarily small positive number $a < \tau_0,$ define the set $K(C_k) = \{ k: 1 \leq |k - k_0| < C_k, aT < k < (1 - a)T \}$. Since $\hat{k} - k_0$ is stochastically bounded, we only consider the values of $k$ that belong to set $K(C_k)$.

Let $\lambda_1(k)$ be the minimum eigenvalue of $\frac{1}{N} \sum_{i=1}^{N} R'(X_{\Delta i}' X_{\Delta i}) R$. Define $\lambda_1 = \min_{k \in K(C_k)} \lambda_1(k)$. Under Assumption 5, $\lambda_1(k) > 0$ and $\lambda_1 > 0$. 

29
Lemma 1 Under Assumptions 1-7, for all large $N$ and $T$, with probability tending to 1,

\[
\inf_{K(C_k)} \sum_{i=1}^{N} J_{i1}(k) \geq \lambda_1 \phi_N.
\]

This lemma is similar to Lemma A.2 in Bai (1997a). The proof can be found in the Supplementary Appendix.

Lemma 2 Under Assumptions 1-7, uniformly on $K(C_k)$,

(i) $\sum_{i=1}^{N} \delta_i' Z_{\Delta i} \varepsilon_i = O_p(\sqrt{\phi_N})$;
(ii) $\frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' Z_{\Delta i} X_i (\frac{X_i' X_i}{T})_{-1} \frac{X_i' \varepsilon_i}{\sqrt{T}} = O_p(\sqrt{\phi_N})$;
(iii) $\frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' (Z_{\Delta i} M_i Z_{2i}) (\frac{Z_{0i}' M_i Z_{2i}}{T})_{-1} \frac{Z_{0i}' M_i \varepsilon_i}{\sqrt{T}} = O_p(\sqrt{\phi_N})$;
(iv) $\frac{1}{T} \sum_{i=1}^{N} \varepsilon_i' M_i Z_{\Delta i} (\frac{Z_{0i}' M_i Z_{2i}}{T})_{-1} Z_{\Delta i} M_i \varepsilon_i = O_p(\frac{N}{T})$;
(v) $\frac{1}{T} \sum_{i=1}^{N} \varepsilon_i' M_i Z_{0i} (\frac{Z_{0i}' M_i Z_{2i}}{T})_{-1} Z_{\Delta i} M_i \varepsilon_i = O_p(\frac{N}{T}) + O_p(\sqrt{\phi_N})$;
(vi) $\sum_{i=1}^{N} \varepsilon_i' M_i Z_{0i} \left[ (\frac{Z_{0i}' M_i Z_{2i}}{T})_{-1} - (\frac{Z_{0i}' M_i Z_{0i}}{T})_{-1} \right] \frac{Z_{0i}' M_i \varepsilon_i}{\sqrt{T}} = O_p(\frac{N}{T})$.

Proof of Lemma 2. (i) Under Assumption 3, for large $N$,

\[
Var \left( \sum_{i=1}^{N} \delta_i' Z_{\Delta i} \varepsilon_i \right) = \sum_{i=1}^{N} \delta_i' Z_{\Delta i} \Sigma_{\varepsilon_i} Z_{\Delta i} \delta_i.
\]

It can be shown equal to $O(\phi_N)$ under Assumptions 4 to 7, similar to the proof of Lemma 1 in the Supplementary Appendix, implying $\sum_{i=1}^{N} \delta_i' Z_{\Delta i} \varepsilon_i = O_p(\sqrt{\phi_N})$ on $K(C_k)$.

The proofs of Lemma 2(ii)-(vi) are included in the Supplementary Appendix.

With these lemmas, we are ready to prove Theorem 1.

Proof of Theorem 1. To prove $\lim_{(N,T) \to \infty} P(\hat{k} = k_0) = 1$, it is equivalent to showing that for any given $\epsilon > 0$, for both large $T$ and $N$, $P(|\hat{k} - k_0| \geq 1) < \epsilon$. It is sufficient to show that $P \left( \sup_{K(C_k)} \sum_{i=1}^{N} [SV_i(k) - SV_i(k_0)] \geq 0 \right) < \epsilon$, or

\[
P \left( \sup_{K(C_k)} \left\| \sum_{i=1}^{N} J_{2i}(k) \right\| \geq \inf_{K(C_k)} \sum_{i=1}^{N} J_{1i}(k) \right) < \epsilon.
\]

By Lemma 1, it suffices to show $P(\sup_{K(C_k)} \frac{1}{\phi_N} \left| \sum_{i=1}^{N} J_{2i}(k) \right| \geq \lambda_1) < \epsilon$. For any $k \in K(C_k)$,
Consider the first term, $Z_{2i} = Z_{0i} + Z_{\Delta i}$ for $k < k_0$

\[
\sum_{i=1}^{N} \left| 2\delta_i'(Z_{0i}'M_iZ_{2i})(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i - 2\delta_i'Z_{0i}'M_i\epsilon_i \right| \\
+ \left| \sum_{i=1}^{N} \left[ \epsilon_i'M_iZ_{2i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i - \epsilon_i'M_iZ_{0i}(Z_{0i}'M_iZ_{0i})^{-1}Z_{0i}'M_i\epsilon_i \right] \right|.
\]

By (i), (ii) and (iii) of Lemma 2, the first term

\[
\sum_{i=1}^{N} \left| 2\delta_i'(Z_{0i}'M_iZ_{2i})(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i - 2\delta_i'Z_{0i}'M_i\epsilon_i \right| = O_p(\sqrt{\phi_N}).
\] (32)

Now consider the second term

\[
\sum_{i=1}^{N} \left| \epsilon_i'M_iZ_{2i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i - \epsilon_i'M_iZ_{0i}(Z_{0i}'M_iZ_{0i})^{-1}Z_{0i}'M_i\epsilon_i \right| \\
\leq \frac{1}{T} \sum_{i=1}^{N} \left| \epsilon_i'M_iZ_{\Delta i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{\Delta i}'M_i\epsilon_i \right| + \frac{2}{\sqrt{T}} \left| \sum_{i=1}^{N} \frac{\epsilon_i'M_iZ_{0i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i}{\sqrt{T}} \right| \\
+ \left| \sum_{i=1}^{N} \frac{\epsilon_i'M_iZ_{0i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{0i}'M_i\epsilon_i}{\sqrt{T}} \right|.
\]

Similarly, by (iv), (v) and (vi) of Lemma 2, the second term

\[
\sum_{i=1}^{N} \left| \epsilon_i'M_iZ_{2i}(Z_{2i}'M_iZ_{2i})^{-1}Z_{2i}'M_i\epsilon_i - \epsilon_i'M_iZ_{0i}(Z_{0i}'M_iZ_{0i})^{-1}Z_{0i}'M_i\epsilon_i \right| = O_p(\frac{N}{T}) + O_p(\sqrt{\frac{N}{T}}).
\] (33)

Combining (32) and (33), we obtain

\[
\frac{1}{\phi_N} \left| \sum_{i=1}^{N} J_{2i}(k) \right| = \frac{1}{\phi_N} \left[ O_p(\sqrt{\phi_N}) + O_p(\frac{N}{T}) + O_p(\sqrt{\frac{N}{T}} \right] = O_p(\frac{1}{\sqrt{\phi_N}}) + \frac{1}{\phi_N} \left[ O_p(\frac{N}{T}) + O_p(\sqrt{\frac{N}{T}} \right] .
\]

Under Assumption 2, \( \frac{1}{\phi_N} \left| \sum_{i=1}^{N} J_{2i}(k) \right| \) vanishes for any $k \in K(C_k)$, so does its maximum.
Compared with (8) of Model 1, (21) of Model 2 has the same form using transformed data \(\{\hat{Y}_i, \hat{X}_i, i = 1, \ldots, N\}\), except for the additional term \(M_wF\gamma_i\). The focus of the proof of Theorem 2 is on showing that \(M_wF\gamma_i\) can be ignored asymptotically as \((N, T) \to \infty\).

For \(i = 1, \ldots, N\), let \(\hat{SSR}_i\) be the sum of squared residuals of regressing \(\hat{Y}_i\) on \(\hat{X}_i\) alone. Using the identity \(\hat{SSR}_i - \hat{SSR}_i(k) = \hat{\delta}_i(k)'[\hat{Z}_{2i}(k)']\hat{M}_i\hat{Z}_{2i}(k)\hat{\delta}_i(k)\) with \(\hat{M}_i = I - \hat{X}_i(\hat{X}_i'\hat{X}_i)^{-1}\hat{X}_i'\), we obtain

\[
\hat{k} = \arg \min_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i \hat{SSR}_i(k) = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i \hat{SV}_i(k) = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^{N} \pi_i [\hat{SV}_i(k) - \hat{SV}_i(k_0)]
\]

where \(\hat{SV}_i(k) = \hat{\delta}_i(k)'[\hat{Z}_{2i}(k)'\hat{M}_i\hat{Z}_{2i}(k)\hat{\delta}_i(k)\). Assume \(\pi_i = 1/N, i = 1, \ldots, N\) for simplicity. The rest proof proceeds in the same way as that of Theorem 1 using the new notations with "\(\hat{\cdot}\)".

Partitioned regression gives

\[
\hat{\delta}_i(k) = \left[\hat{Z}_{2i}(k)'\hat{M}_i\hat{Z}_{2i}(k)\right]^{-1}\hat{Z}_{2i}(k)'\hat{M}_i\hat{Y}_i.
\]

Substituting \(\hat{Y}_i = \hat{X}_i\beta_i + \hat{Z}_0i\delta_i + \hat{\varepsilon}_i^0\) into the equation above, we obtain

\[
\hat{\delta}_i(k) = \left[\hat{Z}_{2i}(k)'\hat{M}_i\hat{Z}_{2i}(k)\right]^{-1}\hat{Z}_{2i}(k)'\hat{M}_i\hat{Z}_0i\delta_i + \left[\hat{Z}_{2i}(k)'\hat{M}_i\hat{Z}_{2i}(k)\right]^{-1}\hat{Z}_{2i}(k)'\hat{M}_i\hat{\varepsilon}_i^0
\]

and \(\hat{\delta}_i(k_0) = \delta_i + \left(\hat{Z}_0'i\hat{M}_i\hat{Z}_0i\right)^{-1}\hat{Z}_0'i\hat{M}_i\hat{\varepsilon}_i^0\). Note that there is an additional term \(M_wF\gamma_i\) in \(\hat{\varepsilon}_i^0 = M_wF\gamma_i + \hat{\varepsilon}_i\).

As in the proof of Theorem 1, we suppress \(k\) in \(\hat{\delta}_i(k)\) and \(\hat{Z}_{2i}(k)\) for simplicity. Since

\[
\hat{SV}_i(k) = \hat{\delta}_i'\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\hat{\delta}_i
\]

\[
= \hat{\delta}_i'\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\left(\hat{Z}_2i'M_i\hat{Z}_2i\right)^{-1}(\hat{Z}_2i'M_i\hat{Z}_0i)\delta_i
\]

\[
+ 2\hat{\delta}_i'\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\left(\hat{Z}_2i'M_i\hat{Z}_2i\right)^{-1}\hat{Z}_2i'M_i\hat{\varepsilon}_i^0 + \hat{\varepsilon}_i^0\hat{M}_i\hat{Z}_0i\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)^{-1}\hat{Z}_2i'M_i\hat{\varepsilon}_i^0,
\]

and \(\hat{SV}_i(k_0) = \hat{\delta}_i'\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\delta_i + 2\hat{\delta}_i'\hat{Z}_0i'\hat{M}_i\hat{\varepsilon}_i^0 + \hat{\varepsilon}_i^0\hat{M}_i\hat{Z}_0i\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_0i\right)^{-1}\hat{Z}_0i'M_i\hat{\varepsilon}_i^0\), it follows that

\[
\hat{SV}_i(k) - \hat{SV}_i(k_0) = \hat{\delta}_i'\left[\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\left(\hat{Z}_2i'M_i\hat{Z}_2i\right)^{-1}(\hat{Z}_2i'M_i\hat{Z}_0i) - (\hat{Z}_0'i\hat{M}_i\hat{Z}_0i)\right]\delta_i
\]

\[
+ 2\hat{\delta}_i'\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_2i\right)\left(\hat{Z}_2i'M_i\hat{Z}_2i\right)^{-1}\hat{Z}_2i'M_i\hat{\varepsilon}_i^0 - 2\hat{\delta}_i'\hat{Z}_0i'M_i\hat{\varepsilon}_i^0
\]

\[
+ \hat{\varepsilon}_i^0\hat{M}_i\hat{Z}_2i\left(\hat{Z}_2i'M_i\hat{Z}_2i\right)^{-1}\hat{Z}_2i'M_i\hat{\varepsilon}_i^0 - \hat{\varepsilon}_i^0\hat{M}_i\hat{Z}_0i\left(\hat{Z}_0'i\hat{M}_i\hat{Z}_0i\right)^{-1}\hat{Z}_0i'M_i\hat{\varepsilon}_i^0.
\]
Define
\[ \tilde{J}_1(k) = \delta_i'(Z_0i'M_i\tilde{Z}_0i) - (\tilde{Z}_0i'M_i\tilde{Z}_2i)(\tilde{Z}_2i'M_i\tilde{Z}_2i)^{-1}(\tilde{Z}_2i'M_i\tilde{Z}_0i)\delta_i. \]

In addition, define
\[ \tilde{J}_2(k) = 2\delta_i'(\tilde{Z}_0i'M_i\tilde{Z}_2i)(\tilde{Z}_2i'M_i\tilde{Z}_2i)^{-1}\tilde{Z}_2i'M_i\tilde{Z}_i - 2\delta_i'(Z_0i'M_i\tilde{Z}_i) - \xi_i'M_i\tilde{Z}_i - \xi_i'M_i\tilde{Z}_0i(\tilde{Z}_0i'M_i\tilde{Z}_0i)^{-1}\tilde{Z}_0i'M_i\tilde{Z}_i. \]

Thus, \( \tilde{SV}_i(k) - \tilde{SV}_i(k_0) = -\tilde{J}_1(k) + \tilde{J}_2(k) \) and
\[ \tilde{k} = \arg \max_{1 \leq k \leq T-1} \sum_{i=1}^N [\tilde{SV}_i(k) - \tilde{SV}_i(k_0)] = \arg \max_{1 \leq k \leq T-1} \left[ -\sum_{i=1}^N \tilde{J}_1(k) + \sum_{i=1}^N \tilde{J}_2(k) \right]. \]

For each \( i, i = 1, \cdots, N \), define \( \tilde{Z}_{\Delta i} = \tilde{Z}_2i(k) - \tilde{Z}_2i(k_0) \) for \( k < k_0 \) and \( \tilde{Z}_2i(k_0) - \tilde{Z}_2i(k) \) for \( k \geq k_0 \). Since \( Z_0i = X_0iR \) and \( Z_2i = X_2iR, \tilde{Z}_{\Delta i} = M_wZ_{\Delta i} = M_wX_{\Delta i}R = \tilde{X}_{\Delta i}R \).

As in the proof of Theorem 1, we assume that \( k - k_0 \) is stochastically bounded, and only consider the values of \( k \) belonging to the set \( K(C_k) = \{ k : 1 \leq |k - k_0| < C_k, aT < k < (1 - a)T \} \).

Let \( \hat{\lambda}_1(k) \) be the minimum eigenvalue of \( \frac{1}{N} \sum_{i=1}^N R'(\tilde{X}_{\Delta i}\tilde{X}_{\Delta i})R \). Define \( \hat{\lambda}_1 = \min_{k \in K(C_k)} \hat{\lambda}_1(k) \). Under Assumption 14, \( \hat{\lambda}_1(k) > 0 \) and \( \hat{\lambda}_1 > 0 \).

**Lemma 3** Under Assumptions 1, 2, 8-15 (or 16), for all large \( N \) and \( T \), with probability tending to 1,
\[ \inf_{K(C_k)} \sum_{i=1}^N \tilde{J}_1(k) \geq \hat{\lambda}_1 \phi_N. \]

Lemma 3 can be shown in the same way as Lemma 1 using the transformed data or the "-" notation. See the Supplementary Appendix.

Different from Model 1, there is an extra term \( M_wF_{\gamma i} \) in the error \( \tilde{e}_i^0 \), thus in \( \tilde{J}_2(k) \). To examine the effect of this extra term on the estimated \( \tilde{k} \) and \( \hat{b}_i \), we introduce some new matrix notation. Since \( x_{it} = \Gamma_i\tilde{f}_t + v_{it} \) in (3), we write
\[ X_i = F_{\Delta i} + V_i. \]
where $V_i = (v_{i1}, \ldots, v_{iT})'$. Denote $F_0 = (0, \ldots, 0, f_{k_0+1}, \ldots, f_T)'$ and $V_{0i} = (0, \ldots, 0, v_{i,k_0+1}, \ldots, v_{i,T})'$. Thus,

$$X_{0i} = (0, \ldots, 0, x_{i,k_0+1}, \ldots, x_{iT})' = (0, \ldots, 0, \Gamma_i'f_{k_0+1} + v_{i,k_0+1}, \ldots, \Gamma_i'f_T + v_{i,T})' = F_0\Gamma_i + V_{0i}.$$ 

For the error term (18), denote $\bar{u}_t = \left( \bar{\varepsilon}_t + \sum_{i=1}^N \theta_i v_i'R_i \right)$ and

$$\Delta\bar{u}_t(k_0) = \begin{cases} \left( \begin{array}{c} 0 \\ 0 \\
\sum_{i=1}^N \theta_i v_i'R_i \\
0 \end{array} \right), & t = 1, \ldots, k_0, \\
0, & t = k_0 + 1, \ldots, T. \end{cases}$$

Thus, $\bar{u}_t(k_0) = \sum_{i=1}^N \theta_i u_it(k_0) = \bar{u}_t + \Delta\bar{u}_t(k_0)$. Denote $\bar{U} = (\bar{u}_1, \ldots, \bar{u}_T)'$ and $\Delta\bar{U}(k_0) = \left( \left( \begin{array}{c} 0 \\ \vdots \\
\sum_{i=1}^N \theta_i v_i'+R_i \\
0 \end{array} \right), \ldots, \left( \sum_{i=1}^N \theta_i v_i'+R_i \right) \right)'$.

Thus, stacking cross-sectional averages $\bar{w}_t = \bar{C}(k_0)'f_t + \bar{u}_t(k_0)$, we obtain

$$\bar{W}_{T \times (p+1)} = (\bar{w}_1, \ldots, \bar{w}_{k_0}, \bar{w}_{k_0+1}, \ldots, \bar{w}_T)' = (\bar{C}_1'f_1 + \bar{u}_1, \ldots, \bar{C}_1'f_{k_0} + \bar{u}_{k_0}, \bar{C}_2'f_{k_0+1} + \bar{u}_{k_0+1}, \ldots, \bar{C}_2'f_T + \bar{u}_T)' = F\bar{C}_1 + F_0(\bar{C}_2 - \bar{C}_1) + \bar{U} + \Delta\bar{U}(k_0).$$

Denote $\mathbb{F} = (F, F_0)$, $\mathbb{C} = (\bar{C}_1, (\bar{C}_2 - \bar{C}_1))'$ and $\bar{W}_{T \times (p+1)} = \bar{U} + \Delta\bar{U}(k_0)$. Therefore,

$$\bar{W} = \mathbb{F}\mathbb{C} + \bar{U}. \quad (34)$$

With this notation, we obtain a lemma, which can be proved similarly to Lemmas 1, 2 and 3 in Pesaran (2006).

**Lemma 4** Under Assumptions 1, 2, 8-15, uniformly on $K(C_k)$,

(i) $\bar{u}_t = O_p(\frac{1}{\sqrt{N}})$, $\Delta\bar{u}_t(k_0) = O_p(\frac{1}{\sqrt{N}})$;

(ii) $\frac{1}{T} \bar{U}'\bar{U} = O_p(\frac{1}{\sqrt{N}})$; $\frac{1}{T} \mathbb{F}'\mathbb{F} = O_p(\frac{1}{\sqrt{NT}})$; $\frac{1}{T} V_i'\mathbb{F} = O_p(\frac{1}{\sqrt{T}})$;

(iii) $\frac{1}{T} V_i'\bar{U} = O_p(\frac{1}{\sqrt{N}} + O_p(\frac{1}{\sqrt{NT}}))$; $\frac{1}{T} \varepsilon_i'\bar{U} = O_p(\frac{1}{\sqrt{N}}) + O_p(\frac{1}{\sqrt{NT}})$; $\frac{1}{T} V_i'\bar{U} = O_p(\frac{1}{\sqrt{N}}) + O_p(\frac{1}{\sqrt{NT}})$; $\frac{1}{T} X_i'\bar{U} = O_p(\frac{1}{\sqrt{N}})$; $\frac{1}{T} X_i'\bar{U} = O_p(\frac{1}{\sqrt{N}})$.

34
Lemma 5  Under Assumptions 1, 2, 8-15, uniformly on $K(C_k)$,

(i) $\frac{1}{T} F' F = O_p(1)$; $\frac{1}{T} F = O_p(1)$;

(ii) $\frac{1}{T} X_i' F = O_p(1)$; $\frac{1}{T} X_i(k)' F = O_p(1)$.

Proof of Lemma 5. (i) is obvious by Assumption 8.

(ii) Since $X_i = F \Gamma_i + V_i = (F, F_0)(\Gamma_i, 0)' + V_i$, $\frac{1}{T} X_i' F$ can be written as $(\Gamma_i, 0)(\frac{1}{T} F' F) + \frac{1}{T} V_i' F$.

By (i) and Lemma 4 (iv), $\frac{1}{T} X_i' F = O_p(1)$. Similarly, $\frac{1}{T} X_i(k)' F = O_p(1)$.

With Lemmas 4 and 5, we are ready to establish the property of the $T \times m$ matrix $M_u F \gamma_i$, which will be frequently used in the derivations below. Denote

$$
\frac{E}{(p+1) \times (p+1)} = \frac{1}{T} C' F' U + \frac{1}{T} U' F C + \frac{1}{T} U' U;
$$

$$
\frac{f(E)}{(p+1) \times (p+1)} = \sum_{k=1}^{\infty} (-1)^{k+1} \left[ \left( \frac{1}{T} C' F' F C \right)^{-1} E \right] \left \{ \frac{1}{T} C' F' F C \right \}^{-1}.
$$

By Lemma 5 (v), $E = O_p(\frac{1}{N}) + O_p(\frac{1}{\sqrt{NT}})$, thus $f(E) = O_p(\frac{1}{N}) + O_p(\frac{1}{\sqrt{NT}})$. In addition, denote

$$
D_{1} = -C f(E) C \frac{F' F}{T} + C \left \{ (C' F' F C)^{-1} + f(E) \right \} \frac{U' F}{T} \quad \text{(35)}
$$

and

$$
D_{2} = -\left[ (C' F' F C)^{-1} + f(E) \right] \left \{ (C' F' F C)^{-1} + \frac{U' F}{T} \right \}. \quad \text{(36)}
$$

Since $C = O(1)$, $\frac{F' F}{T}$ and $\frac{F' F}{T}$ are $O_p(1)$, $f(E) = O_p(\frac{1}{N}) + O_p(\frac{1}{\sqrt{NT}})$, and $\frac{U' F}{T} = O_p(\frac{1}{\sqrt{NT}})$,

$$
D_{1} = O_p(1) \left \{ O_p\left( \frac{1}{N} \right) + O_p\left( \frac{1}{\sqrt{NT}} \right) \right \} O_p(1) + O_p(1) \left \{ O_p\left( \frac{1}{N} \right) + O_p\left( \frac{1}{\sqrt{NT}} \right) \right \} O_p\left( \frac{1}{\sqrt{NT}} \right) = O_p\left( \frac{1}{N} \right) + O_p\left( \frac{1}{\sqrt{NT}} \right).
$$

Similarly,

$$
D_{2} = O_p(1) + O_p\left( \frac{1}{N} \right) + O_p\left( \frac{1}{\sqrt{NT}} \right) = O_p(1).
$$

Lemma 6  Under Assumptions 1, 2, 8-15, uniformly on $K(C_k)$,

$$
M_u F \gamma_i = \mathbb{F} D_1 \gamma_i + \mathbb{U} D_2 \gamma_i.
$$
By Lemma 4 (i) where each element of $\bar{U}$ is $O_p(\frac{1}{\sqrt{N}})$, each element of $M_w F \gamma_i$ is of order $O_p(\frac{1}{\sqrt{N}})$.

**Proof of Lemma 6.** Plugging in (34), we obtain

$$\frac{1}{T} \bar{W}' \bar{W} = \frac{1}{T} \bar{C}' \bar{F}' \bar{F} \bar{C} + \frac{1}{T} \bar{C}' \bar{F}' \bar{U} + \frac{1}{T} \bar{U}' \bar{F} \bar{C} + \frac{1}{T} \bar{U}' \bar{U} = \frac{1}{T} \bar{C}' \bar{F}' \bar{C} + E.$$

By Lemma 5 (i), $\frac{1}{T} \bar{C}' \bar{F}' \bar{C}$ is $O_p(1)$. Since $E = O_p(\frac{1}{N}) + O_p(\frac{1}{NT})$, it could be very small when both $N$ and $T$ are large. By Horn and Johnson (1985, p.335)

$$\frac{1}{T} \bar{C}' \bar{F}' \bar{C} - \left( \frac{1}{T} \bar{W}' \bar{W} \right)^{-1} = \frac{1}{T} \bar{C}' \bar{F}' \bar{C} - \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} + E \right)^{-1}$$

$$= \frac{1}{T} \bar{C}' \bar{F}' \bar{C} - \left[ I + \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} E \right]^{-1} \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1}$$

$$= \sum_{k=1}^{\infty} (-1)^{k+1} \left[ \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} E \right]^k \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} = f(E).$$

This yields

$$\frac{1}{T} \bar{W}' \bar{W} = \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} + f(E).$$

It follows that

$$M_w F = [I_T - \bar{W} \left( \frac{1}{T} \bar{W}' \bar{W} \right)^{-1} \frac{1}{T} \bar{W}' \bar{F}] = [I_T - (\bar{F} \bar{C} + \bar{U}) \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} + f(E) \left( \frac{1}{T} \bar{F} \bar{C} \right)^{-1} \frac{1}{T} \bar{U}' \bar{F}]$$

$$= [I_T - (\bar{F} \bar{C}) (\bar{C}' \bar{F}' \bar{C})^{-1} (\bar{F} \bar{C})' \bar{F} - (\bar{F} \bar{C}) (f(E) \left( \frac{1}{T} \bar{F} \bar{C} \right)' + \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} + f(E) \left( \frac{1}{T} \bar{F} \bar{C} \right)^{-1} \frac{1}{T} \bar{U}') F$$

$$- \bar{U} \left( \frac{1}{T} \bar{C}' \bar{F}' \bar{C} \right)^{-1} + f(E) \left( \frac{1}{T} \bar{F} \bar{C} + \frac{1}{T} \bar{U}' \bar{F} \right)$$

As discussed in Pesaran (2006), $M_{wC} = I_T - (\bar{F} \bar{C}) (\bar{C}' \bar{F}' \bar{C})^{-1} (\bar{F} \bar{C})' = I_T - \bar{F} (\bar{F}' \bar{F})^{-1} \bar{F}$ under the rank assumption. This implies that the first term is 0. Therefore, plugging in (35) and (36), we obtain

$$M_w F \gamma_i = \bar{F} D_1 \gamma_i + \bar{U} D_2 \gamma_i.$$  

(37)

The following lemma collects terms involving $M_w F \gamma_i$.

**Lemma 7** Under Assumptions 1, 2, 8-15 (or 16), uniformly on $K(C_k)$,
(i) \( \sum_{i=1}^{N} \delta'_i \tilde{Z}'_{\Delta_i} M_u F \gamma_i = O_p(\sqrt{\phi_N}) \);

(ii) \( \frac{1}{T} \sum_{i=1}^{N} \delta'_i \tilde{Z}'_{\Delta_i} \tilde{X}_i (\tilde{\tilde{X}}_i)^{-1} \tilde{X}_i' M_u F \gamma_i = O_p(\sqrt{\frac{\phi_N}{NT}}) + O_p(\sqrt{\frac{\phi_N}{T}}) \);

(iii) \( \frac{1}{T} \sum_{i=1}^{N} \delta'_i (\tilde{Z}'_{\Delta_i} M \tilde{Z}_{2i}) (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i} M_u F \gamma_i = O_p(\sqrt{\frac{\phi_N}{NT}}) + O_p(\sqrt{\frac{\phi_N}{T}}) \);

(iv) \( \frac{1}{T} \sum_{i=1}^{N} \delta'_i \tilde{Z}_{\Delta_i} M_u F \gamma_i = O_p(\frac{1}{T}) \);

b. \( \frac{1}{T} \sum_{i=1}^{N} \tilde{Z}_{\Delta_i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) \);

(v) \( \frac{1}{T} \sum_{i=1}^{N} \varepsilon'_i M \tilde{Z}_0 (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) \);

b. \( \frac{1}{T} \sum_{i=1}^{N} \gamma'_i F'M_u \tilde{M}_i \tilde{Z}_0 (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) \);

c. \( \frac{1}{T} \sum_{i=1}^{N} \gamma'_i F'M_u \tilde{M}_i \tilde{Z}_0 (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) + O_p\left(\frac{1}{T}\right) \);

(vi) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \varepsilon'_i M \tilde{Z}_0 \left[ (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} - (\tilde{Z}_{0i} M \tilde{Z}_{0i})^{-1} \right] \tilde{Z}_{0i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{NT}}\right) + O_p\left(\frac{1}{T}\right) \);

b. \( \frac{1}{T} \sum_{i=1}^{N} \gamma'_i F'M_u \tilde{M}_i \tilde{Z}_0 \left[ (\tilde{Z}_{2i}^2 M \tilde{Z}_{2i})^{-1} - (\tilde{Z}_{0i} M \tilde{Z}_{0i})^{-1} \right] \tilde{Z}_{0i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) + O_p\left(\frac{1}{T}\right) \)

Proof of Lemma 7.

(i) Consider the term

\[ \tilde{Z}'_{\Delta_i} M_u F \gamma_i = Z'_{\Delta_i} M_u F \gamma_i = Z'_{\Delta_i} \mathbb{F} D_1 \gamma_i + Z'_{\Delta_i} \bar{U} D_2 \gamma_i. \]

Since there are \(|k - k_0|\) non-zero elements in \(Z_{\Delta_i}\), \(Z'_{\Delta_i} \mathbb{F}\) is equal to the sum of \(|k - k_0|\) elements, and is finite on \(K(C_k)\). Similarly, \(Z'_{\Delta_i} \bar{U}\) is also equal to the sum of \(|k - k_0|\) elements, each is \(O_p\left(\frac{1}{\sqrt{T}}\right)\). Due to the fact that \(D_1 = O_p\left(\frac{1}{\sqrt{T}}\right) + O_p\left(\frac{1}{\sqrt{NT}}\right)\) and \(D_2 = O_p(1)\),

\[ Z'_{\Delta_i} M_u F \gamma_i = O_p\left(\frac{1}{\sqrt{T}}\right) + O_p\left(\frac{1}{\sqrt{NT}}\right) + O_p\left(\frac{1}{\sqrt{N}}\right) = O_p\left(\frac{1}{\sqrt{N}}\right). \]

Therefore,

\[ \sum_{i=1}^{N} \delta'_i \tilde{Z}'_{\Delta_i} M_u F \gamma_i = O_p\left(\sqrt{N\phi_N}\right) O_p\left(\frac{1}{\sqrt{N}}\right) = O_p\left(\sqrt{\phi_N}\right). \]

The rest of this lemma can be proved similarly. See the Supplementary Appendix for a detailed proof.

Lemma 2 in Model 1 can be extended to Model 2 using transformed data as Lemma 8.

**Lemma 8** Under Assumptions 1, 2, 8-15 (or 16), uniformly on \(K(C_k)\),
(i) \( \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i = O_p(\sqrt{\phi_N}) \);
(ii) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{X}_i \left( \frac{\tilde{X}_i \tilde{X}_i}{T} \right)^{-1} = O_p(\sqrt{\phi_N}) \);
(iii) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' \left( (\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i}) \left( \frac{\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i}}{T} \right)^{-1} \frac{\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i}{\sqrt{T}} \right) = O_p(\sqrt{\phi_N}) \);
(iv) \( \frac{1}{T} \sum_{i=1}^{N} \tilde{e}_i' \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i = O_p(\frac{N}{T}) \);
(v) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \frac{\tilde{e}_i' \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i}{\sqrt{T}} = O_p(\frac{N}{T}) \); starts with \( O_p(\frac{N}{T}) \) + \( \frac{1}{\sqrt{N}} \) terms involving \( M_w F \gamma_i \)
Lemma 7 are used to obtain the following lemma.

Lemma 9 Under Assumptions 1, 2, 8-15 (or 16), uniformly on \( K(C_k) \),

(i) \( \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i = O_p(\sqrt{\phi_N}) \);
(ii) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{X}_i \left( \frac{\tilde{X}_i \tilde{X}_i}{T} \right)^{-1} = O_p(\sqrt{\phi_N}) \); starts with \( O_p(\sqrt{\phi_N}) \)
(iii) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \delta_i' \left( (\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i}) \left( \frac{\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i}}{T} \right)^{-1} \frac{\tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i}{\sqrt{T}} \right) = O_p(\sqrt{\phi_N}) \);
(iv) \( \frac{1}{T} \sum_{i=1}^{N} \tilde{e}_i' \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i = O_p(\frac{N}{T}) \);
(v) \( \frac{1}{\sqrt{T}} \sum_{i=1}^{N} \frac{\tilde{e}_i' \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{Z}_{\Delta_i} \tilde{Z}_{\Delta_i} \tilde{M}_i \tilde{e}_i}{\sqrt{T}} = O_p(\frac{N}{T}) \); starts with \( O_p(\sqrt{\phi_N}) \)
Proof of Lemma 9. (i) Plugging in \( \tilde{e}_i = M_w F \gamma_i + \tilde{e}_i \), we obtain

\[
\sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i = \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} M_w F \gamma_i + \sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i
\]

Lemma 7(i) shows that the first term is \( O_p(\sqrt{\phi_N}) \). By Lemma 8 (i), the second term

\[
\sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i = O_p(\sqrt{\phi_N})
\]

uniformly on \( K(C_k) \). It follows that

\[
\sum_{i=1}^{N} \delta_i' \tilde{Z}_{\Delta_i} \tilde{e}_i = O_p(\sqrt{\phi_N}) + O_p(\sqrt{\phi_N}) = O_p(\sqrt{\phi_N}).
\]

The proofs of Lemma 9(ii)-(vi) are included in the Supplementary Appendix.
With these lemmas, we are ready to prove Theorem 2.

**Proof of Theorem 2.** To prove \( \lim_{(N,T) \to \infty} P(\bar{k} = k_0) = 1 \), it is equivalent to show that for any given \( \epsilon > 0 \), for both large \( T \) and \( N \), \( P(|\bar{k} - k_0| \geq 1) < \epsilon \). It is sufficient to show that

\[
P \left( \sup_{K(C_k)} \left[ \sum_{i=1}^{N} \left( \widehat{S}V_i(k) - \widehat{S}V_i(k_0) \right) \right] \geq 0 \right) < \epsilon,
\]

or

\[
P \left( \sup_{K(C_k)} \left[ \sum_{i=1}^{N} \tilde{j}_{2i}(k) \right] \geq \inf_{K(C_k)} \left[ \sum_{i=1}^{N} \tilde{j}_{1i}(k) \right] \right) < \epsilon.
\]

By Lemma 3, it is sufficient to show

\[
P \left( \sup_{K(C_k)} \frac{1}{\phi_N} \left[ \sum_{i=1}^{N} \tilde{j}_{2i}(k) \right] \geq \lambda_1 \right) < \epsilon.
\]

For any \( k \in K(C_k) \),

\[
\left| \sum_{i=1}^{N} \tilde{j}_{2i}(k) \right| \leq \sum_{i=1}^{N} \left[ 2\delta'_i(\tilde{Z}'_0, M_i, \tilde{Z}_2)(\tilde{Z}'_2, M_i, \tilde{Z}_2)^{-1} \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 - 2\delta'_i \tilde{Z}'_0, \bar{M}_i \bar{\varepsilon}_i^0 \right]
\]

\[
+ \sum_{i=1}^{N} \left[ \bar{\varepsilon}_i^0 M_i \tilde{Z}_2 (\tilde{Z}'_2, M_i, \tilde{Z}_2)^{-1} \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 - \bar{\varepsilon}_i^0 M_i \tilde{Z}_2 (\tilde{Z}'_0, M_i, \tilde{Z}_2)^{-1} \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 \right].
\]

Consider the first term, with \( \tilde{Z}_2 = \tilde{Z}_0 \pm \tilde{Z}_2 \),

\[
\leq 2 \sum_{i=1}^{N} \left| \delta'_i \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 \right| + \frac{2}{\sqrt{T}} \sum_{i=1}^{N} \delta'_i \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 \left( \sum_{i=1}^{N} \delta'_i \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 \right)^{-1} \frac{\tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0}{\sqrt{T}}
\]

\[
+ \frac{2}{\sqrt{T}} \sum_{i=1}^{N} \delta'_i \left( \tilde{Z}'_{2i} \bar{M}_i \tilde{Z}_2 (\tilde{Z}'_2, M_i, \tilde{Z}_2)^{-1} \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 \right). \]

By (i), (ii) and (iii) of Lemma 9, the first term

\[
\sum_{i=1}^{N} \left[ 2\delta'_i(\tilde{Z}'_0, M_i, \tilde{Z}_2)(\tilde{Z}'_2, M_i, \tilde{Z}_2)^{-1} \tilde{Z}'_{0i} \bar{M}_i \bar{\varepsilon}_i^0 - 2\delta'_i \tilde{Z}'_0, \bar{M}_i \bar{\varepsilon}_i^0 \right] = O_p(\sqrt{\phi_N}).
\]
Now consider the second term

\[
\sum_{i=1}^{N} \left[ \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{2i} (\tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_i - \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{0i} (\tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_{0i})^{-1} \tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_i \right]
\]

\[
\leq \frac{1}{T} \left| \sum_{i=1}^{N} \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{0i} \left( \frac{\tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_{2i}}{T} \right)^{-1} \tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_i \right|
\]

\[
+ 2 \frac{1}{\sqrt{T}} \left| \sum_{i=1}^{N} \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{0i} \left( \frac{\tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_{2i}}{T} \right)^{-1} \tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_i \tilde{Z}_{0i} \right|
\]

\[
+ \sum_{i=1}^{N} \frac{\tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{0i}}{\sqrt{T}} \left[ \left( \frac{\tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_{2i}}{T} \right)^{-1} - \left( \frac{\tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_{0i}}{T} \right)^{-1} \right] \tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_i \tilde{Z}_{0i} \right|
\]

By (iv), (iv) and (vi) of Lemma 9, the second term

\[
\sum_{i=1}^{N} \left[ \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{2i} (\tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_{2i})^{-1} \tilde{Z}_{2i}^\prime \tilde{M}_i \tilde{Z}_i - \tilde{\varepsilon}_i^0 \tilde{M}_i \tilde{Z}_{0i} (\tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_{0i})^{-1} \tilde{Z}_{0i}^\prime \tilde{M}_i \tilde{Z}_i \right]
\]

\[
= \mathcal{O}_p \left( \frac{N}{T} \right) + \mathcal{O}_p \left( \sqrt{\frac{N}{T}} \right) + \mathcal{O}_p \left( \frac{1}{\sqrt{N}} \right).
\]

Therefore, we get

\[
\frac{1}{\phi_N} \left| \sum_{i=1}^{N} \tilde{J}_{2i}(k) \right| = \frac{1}{\phi_N} \left[ \mathcal{O}_p \left( \sqrt{\phi_N} \right) + \mathcal{O}_p \left( \frac{N}{T} \right) + \mathcal{O}_p \left( \sqrt{\frac{N}{T}} \right) + \mathcal{O}_p \left( \frac{1}{\sqrt{N}} \right) \right]
\]

\[
= \mathcal{O}_p \left( \frac{1}{\sqrt{\phi_N}} \right) + \frac{1}{\phi_N} \left[ \mathcal{O}_p \left( \frac{N}{T} \right) + \mathcal{O}_p \left( \sqrt{\frac{N}{T}} \right) \right] + \frac{1}{\phi_N} \mathcal{O}_p \left( \frac{1}{\sqrt{N}} \right).
\]

Compared with the proof of Theorem 1, there is an extra term \( \frac{1}{\phi_N} \mathcal{O}_p \left( \frac{1}{\sqrt{N}} \right) = o_p(1) \). But, \( \frac{1}{\phi_N} \left| \sum_{i=1}^{N} \tilde{J}_{2i}(k) \right| \) vanishes for any \( k \in K(C_k) \) as \( (N, T) \to \infty \), so does its maximum.
